An Atlas of Human Anatomy for Students and Physicians. By Professor CARL TOLDT, M.D., assisted by ALOIS D. ROSA, M.D. Translated from the third German edition by M. EDEN PAUL, M.D. Brux. Second Section: Arthrology (Figs. 378 to 489 and Index). 1903. Pp. 94. Price 6*s.* net. Third Section: Myology (Figs. 490 to 640 and Index). 1904. Pp. 141. Price 8*s.* 6*d.* net. London: Rebman, Limited.

THE second section of Toldt's Atlas, translated by Dr. Paul, in every way equals in excellence the first. This fasciculus is a small one and is devoted to arthrology only. All joints are fully illustrated from various aspects and the translator has adopted the same system of terminology as in the previous section with the same happy results. We notice that the author does not figure so many facets on the articular surfaces of the femur and patella as is customary among English anatomists and in the shoulder-joint gives no distinct indication of the gleno-humeral bands as ordinarily described. In other respects the illustrations closely follow the conventional lines.

The third section is what it purports to be—*viz.*, an Atlas of Myology—and is practically confined to this subject. The plates showing dissections from superficial to deep parts are admirable but what strikes us is that this arrangement, whereby the muscles are dealt with by themselves and with all reference to the nerves that supply them or the blood-vessels and other structures which lie in relation to them omitted, is one which is rather artificial. There are some excellent plates in a supplement dealing with the anatomy of the inguinal and crural canals in relation to hernia. Practically in these plates alone are the relations of the blood-vessels and adjoining structures figured. We are glad to see the introduction of groups of muscles long since classified together as synergistic and their antagonists acting on a particular joint. A limited number of figures are devoted to the minute structure of muscle. A useful general illustration is given in *Fig.* 505 showing the relations of the fasciæ in a limb to the various muscles and to the bones.

As showing the general plan of the work we may take the plates on the muscles of the back, Figs. 507 to 514. One plate is devoted to the superficial muscles and so on in succession until the deepest structures are reached, and finally there is an outline diagram showing the skeleton on which the origins and insertions of the long and short muscles are indicated by different coloured lines.

Several dissections are shown, more especially of the limbs, in which the attachments only of the muscles to the bones are left and indicated in colour (Figs. 565, 567, 573, 577, 609, 610, and so on). Some of the dissections showing the muscles passing between the lumbar vertebræ and the hip-bone—e.g., Figs. 592 and 594—give views that are not commonly found in English text-books. There is a very complete index.

LIBRARY TABLE.

Africa and National Regeneration. By E. F. CHIDELL. London: Thomas Burleigh. 1904. Pp. 78. Price 1*s.*—The preface to this, the second, edition of this pamphlet is rather longer than the whole of the first edition. The author avers that there is pressing need for the utmost haste in settling in Africa a large population of Britons, where there is land, the best and richest of all her wide inheritance, of which England has not yet abdicated the sovereignty, a land of the size and possibilities of which the home-staying Englishman finds it difficult to form a correct conception. He reminds the public that medical science will ultimately solve the problems presented by tropical diseases and that these advances will much enlarge the profitable range of the white man in Africa. Mr. Chidell writes that "attention has been drawn to the supreme importance of land, to the absolute necessity of it to a State that hopes to play a leading part in human destinies. That England, or the British Empire as at present constituted, can continue to rank for an indefinite time with such coherent and colossal aggregates as Russia, the United States, and perchance before long China, is a supposition unsupported by the facts of the case. For land is the primary need of man; his other material wants resolve themselves into dependence upon it; and the greatness of States is principally measured by it." He advocates the settlement by the State of a population in Africa from the British Isles at the rate of about a million persons a year and offers many suggestions as to how this may be carried out.

Intercolonial Medical Congress of Australasia. Transactions of the Sixth Session held in Hobart, Tasmania, February, 1902. Published under the direction of the Literary Committee by GREGORY SPROTT, M.D. Glasg. Tasmania: John Vail. 1903 Pp. 480.—The delay in issuing these Transactions has been caused by pressure of work in the Government printing office and to some extent by authors not returning proofs as speedily as they might have done. Some of the papers have already been published in various medical journals. In the Introductory Address on Cancer. Dr. H. B. Allen, professor of anatomy and pathology in the University of Melbourne, draws the general conclusions that malignant tumours in young people show no recent sign of increase; that among the external cancers, those of the face and lip in males appear to be less frequent than formerly, while cancer of the breast in women has also decreased; that uterine cancer has only slightly increased, the rates for women under 55 years of age being lower than they were 30 years ago; and that the apparent increase of cancer is most marked in old people and particularly in women aged 75 years and upwards. Dr. Allen is strongly of opinion that most of this apparent increase is fictitious, being due partly to changes in the age distribution of the population and partly to more regular medical examinations, better diagnosis, and more explicit registration. The cancer statistics of Australasia, compared with those of England and Wales, show that the rates are decidedly lower for males and for females, and this both for all ages and at almost every period of life except for persons aged 75 years and upwards. The work of the congress was divided into five sections—viz., Medicine, Surgery, Eye, Ear, and Throat Section, Gynæcology, and Public Health. Excluding the presidential addresses there were contributed 14 papers in the section on medicine, 17 in the surgery section, 13 in the eye, ear, and throat section, 9 in the section on gynæcology, and 12 in the public health section. The papers are printed in this volume; among them is a paper on Adenoids in Adults by Mr W. Kent Hughes of Melbourne. There is a good paper on Some of the Rarer Forms of Eye Diseases met with in Tasmania by Dr. G. Heuzé Hogg of Launceston, which is illustrated. The clinical matter throughout the volume is evidence of the excellent and high-class work which is being done by the practitioners of Australasia.

How to Become a Certified Midwife. By E. L. O. APPEL, M.B., B.S., B.Sc. Lond. London: The Scientific Press, Limited. 1904. Pp. 29. Price 1*s.*—The legal requirements of the Midwives Act differ somewhat in different cases. Dr. Appel in this little book, which is well written and well arranged, sets forth these requirements in such a way that a woman can by referring to the table of contents find those which are applicable to her case. The pamphlet is divided into three chapters. The first chapter deals with certification and how to become certified before March 31st, 1905, and after that date. The second chapter gives the rules and regulations issued by the Central Midwives Board, which the certified midwife will be required to obey. The final chapter deals with her relations and duties, as a certified midwife, to the local authority of the area in which she intends to practise as a midwife. There is an appendix of the names of approved institutions under Section C of the rules of the Central Midwives Board and of institutions the certificates of which are accepted as qualifications under Section 2 of the Act.

JOURNALS AND MAGAZINES.

Medical Electrology and Radiology.—Three articles published in the June number are continued in July—namely, those on the Treatment of Affections of the Gastro-intestinal Tract, by Dr. George Herschell; on the Application of High-frequency Currents, by Mr. C. A. Wright; and the Lectures on Physics applied to Medicine, by Sir Oliver Lodge. The meetings of the British Electrotherapeutic Society are reported at considerable length as usual. The July number also contains articles on the X Rays in the Diagnosis of Joint Conditions and on Treatment by Blue Light.

Caledonian Medical Journal.—The opening article in the July number is a Plea for More Accurate Clinical Observation by Dr. James Mackenzie of Burnley, the author of an excellent work on the study of the pulse by means of various recording instruments such as the sphygmograph. Other contributions are on the Medicinal Plants found in the Scottish Highlands, by Mr. Henry White; on Heredity in the Scottish Highlands, by Mr. A. Macdonald; and on the Use of Alcoholic Beverages in Scotland about the Year 1735—namely, before the consumption of whisky became generalised.

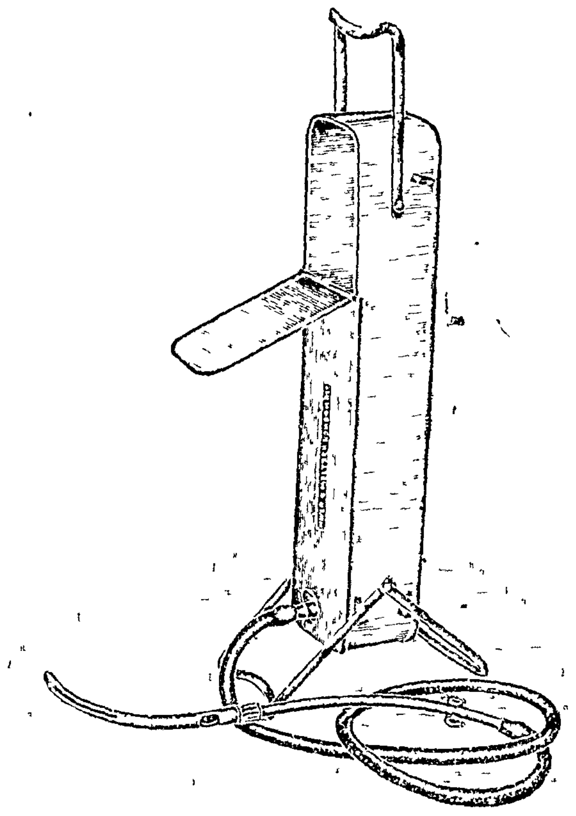
Journal of the Irish Medical Association.—The July number is mainly occupied with a report of the annual general meeting of the Association held in the buildings of the Royal College of Surgeons in Dublin on June 7th. The leading article is on the subject of Superannuation for Poor-law Medical Officers.

New Inventions.

A HANDY AID TO CLEANLY MIDWIFERY.

Believing that any appliance which will make surgical asepsis, and consequently safety, easier of attainment in operative midwifery will be welcomed by the profession at large, especially if it does not entail carrying cumbersome apparatus, I append a description of a combined steriliser and irrigator which I have invented and have found very useful in my own practice. It is not heavy and not bulky, the measurements being 16 × 3½ × 2½ inches. It will therefore go quite easily into any ordinary midwifery bag and the forceps, douche tube, &c., can be packed inside it to save space. It consists of a kind of box, made of sheet copper, tinned inside, and having an opening at one end for five inches of its length, which I have found sufficient for the insertion and removal of any midwifery instrument. Near the other end is a hole, tapped to receive a screwed-in nozzle to which to attach rubber tubing. It is fitted with three supports which fold quite flat when not in use. Nos. 1 and 2 of these form the legs when the instrument is in the horizontal position in use as a steriliser, while Nos. 2 and 3 form a firm base of support when the instrument is in a vertical position in use as an irrigator. No. 1 can in this position be used as a handle or as a suspending loop.

My manner of using the instrument is as follows. On ascertaining that the application of forceps is likely to be necessary I put my forceps (Anderson's or the Barnes-Simpson pattern with metal handles), together with a Bozemann's douche-tube, into the steriliser, pour on boiling water from a kettle, and light the lamp. If the instruments are wanted immediately I usually put a clove hitch of thread on the ends of the handles to facilitate removal, but they can be removed by hand a very short time after boiling if the can be placed vertically first. Having removed them and allowed them to cool in the air till they are cool enough to use I lubricate with biniodide of mercury soap and apply them. By the time the third stage is over the water in the can is probably cool enough to use for douching; if not, as ascertained by thermometer, as cold *boiled* water is not usually available I have added some of the antiseptic (generally potassio-mercuric iodide) to some *cold* water while the instruments were boiling, so that by now the solution is quite aseptic and will produce when mixed with the hot water a solution of about the right strength. *This* having been added to the hot water so as to produce a mixture of the required temperature, the tube is connecte up and the irrigation proceeded with. I know that ther is much diversity of opinion respecting the necessity an even the advisability of douching; but I am speaking no of *operative* cases, and I use a douche in every case in whic my hand or any instrument has been introduced into th uterus. I do not advise the abandonment of our old frien the "Higginson," as it is useful for the preliminary vagina douche and also sometimes for rectal purposes.



The combined steriliser and irrigator has been very neatly made for me in polished copper, tinned inside, by Messrs. Mayer and Meltzer of 71, Great Portland-street, who have carried out my ideas very faithfully and with strict regard to both utility and portability, and to them I am indebted for an improvement upon my original design in the matter of attaching the supports. The steriliser as made is, of course, available for the general purposes of a steriliser as well as for its special use in midwifery cases. Its fluid capacity when standing vertically for use as an irrigator is about four pints.

THE LANCET.

LONDON: SATURDAY, JULY 30, 1904.

The British Medical Association: The President's Address.

FOR the fourth time since its inception the British Medical Association has held its annual meeting in Oxford. At the first meeting in 1835 some 300 members attended, the second meeting was held in 1852, and the third in 1868. At this last meeting the total number of members of the Association was 3672 and some 500 of these were present at Oxford. To-day the Association numbers over 19,000 members and the number of members attending the meeting which commenced on Tuesday, the 26th, is about 1500. In his presidential address, which appears in another column, Dr. **WILLIAM COLLIER** recalls these facts, making them a pendant to the main subject of his address, "The Growth and the Development of the Oxford Medical School."

The teaching of medicine at Oxford is no new thing, for there is a tradition that at some time during the ninth century there was a Jewish School of Medicine existing in Oxford but this of course was before the foundation of the University. During the thirteenth century the great **ROGER BACON** lectured upon various scientific subjects, including probably medicine as it was understood in those days, and met with the reward which is commonly meted out to those who are in advance of their age. Passing over some 200 years it is curious to note that one of Oxford's most famous sons—namely, **LINACRE**—who was a Fellow of All Souls, who lectured on physic and who encouraged the teaching of medicine both at Oxford and Cambridge, was indirectly the cause of the blight which stunted the growth of the medical schools at both these universities by his foundation of the College of Physicians in London. In the seventeenth century the study of medicine at Oxford received enormous impetus through the influence of **HARVEY**, **SCARBURGH**, **WILLIS**, and **WREN** who, though known to everyone as an architect, is almost unknown as an anatomist. But despite great names such as **SYDENHAM** and **RADCLIFFE** the teaching of medicine at Oxford languished although many efforts were made to overcome the hatred, for we can use no other word, with which science was regarded at Oxford. **BUCKLAND**, the eminent geologist, lectured on that subject at Christ Church greatly to the horror of Dean **GAISFORD**. Apart, however, from the subject of his lectures **BUCKLAND** must have been a trying colleague, for he not only kept various wild animals in Tom Quad but also invited his colleagues to dinners at which strange meats such as crocodile and monkey were served. Two years after the return of **ACLAND** to Oxford in 1845 as Lee's reader in anatomy a new era was entered. **ACLAND** conceived the idea of a building under which all departments of the natural sciences should be housed and, for events move slowly in Oxford, eight years later—namely, in 1855—the foundation-stone of the museum was laid by the then Chancellor, the Earl of **DERBY**. This was the beginning of the revival of the Oxford Medical School and it is mainly due to the unremitting toil of **ACLAND** that the medical school has grown to what it now is.

Oxford has been unkindly called "the home of lost causes." It is not within our province to discuss the various political and religious movements which, having their birth in Oxford, profoundly affected the country at large, but the medical school, which at one time indeed seemed "lost," has renewed its youth. It has men and laboratories in which they may work, it has energy and the desire to do good work, but it is poor. The city of Oxford has no rich citizens like those who have given so generously to the Universities of Liverpool and Birmingham, neither can the clinical material for instruction which is available in Oxford compare for one moment with that which is always at hand in London or Edinburgh. But the University possesses one asset which is of incalculable value, the love and remembrance of her sons. There is hardly an Oxford man who will not say of his University,

> "Ille terrarum mihi praeter omnes
> Angulus ridet,"

and it may be that the attention which is now called towards the Oxford Medical School by the meeting of the British Medical Association can be made the foundation of an appeal for offerings towards the better endowment of that school. To heal the sick, to aid in lessening the sum of human misery, and to add even a little to our at best imperfect knowledge of the natural sciences is no unworthy task for that corporation the motto of which is "Dominus illuminatio mea."

The British Medical Association: The Address in Medicine.

IN delivering the Address in Medicine at the annual meeting of the British Medical Association held this year at Oxford Sir **WILLIAM CHURCH** selected as his subject "Our Sanitary Needs, with Special Reference to the National Health." He prefaced his remarks with an allusion to the last occasion on which the Association met at Oxford, namely, in 1868, when addresses were delivered by **ACLAND**, **ROLLESTON**, and **GULL**, who will always be remembered not only as ornaments of our profession but as leaders who accomplished much in the promotion of medical and surgical knowledge. He also pointed out that the meeting in 1868 was for another reason of unusual interest, for it may be taken as marking the date of "the parting of the ways." Up to that period the conceptions of the causes of morbid changes in the body were still practically those introduced by the originators of pathology, **MORGAGNI**, **HUNTER**, **CARSWELL**, and others, and it was only in 1867 that **LISTER** read at Dublin his paper on the antiseptic principle in the practice of surgery; it was at this time also that the possibility of the infectivity of tuberculosis began to be recognised generally. Thus the ground was prepared for the science of bacteriology but it was not until some years later that this branch of medicine was firmly established. The quotations from **GULL'S** address on Clinical Observation in Relation to Medicine in Modern Times showed how great is the abyss which separates the medicine of to-day from that of our immediate predecessors.

Passing to the main subject matter of his address Sir WILLIAM CHURCH proceeded to make some remarks on the principles of preventive medicine, pointing out that the exact knowledge based on scientific research and demonstration which has now been established of the cause and nature of disease has a greater influence on preventive or State medicine than on clinical treatment. It will not be disputed that, in the majority of instances in which the mortality of a disease has been lowered, this has been due to a lessened incidence of the malady brought about by improved hygienic means rather than by the introduction of new therapeutic measures. Sir WILLIAM CHURCH dwelt on the dictum (which cannot be too often repeated) that the health of the people, both bodily and mental, is the principal asset of the nation. Much has lately been said about the deterioration and the degeneration of the British population and we cordially endorse his hope that the committee of the Privy Council on the physical disability of recruits, now engaged in framing its report, may urge on the Government the desirability that a physical census of the nation should be taken from time to time and that the physical condition of the children in our primary schools should be recorded as regularly and carefully as their educational progress. In our opinion the most important note in the address was reached when Sir WILLIAM CHURCH referred to the powers possessed by the medical officers of health and the medical officers of the Local Government Board. There can be no doubt that he is correct when he maintains that neither in the Government nor in the country do they hold the position which they are entitled to command in virtue of their high qualifications and the importance of their duties. The explanation of this fact probably lies in the great ignorance shown by the mass of the population of the principles on which the regulation of the public health depends. The local sanitary authorities are prone to value their own ideas on hygiene more highly than the opinions expressed by the medical officers of health who have been specially trained in such matters, and as the tenure of the professional appointments is in great measure determined by those bodies if the officers have the courage of their convictions and refuse to accede to actions of these authorities undertaken against medical advice, very awkward situations may arise. Dismissal or suspension of a medical officer must be at once reported to the Local Government Board, but this fact does not obviate much trouble. During the past year the Council of the British Medical Association and its medico-political and public health committees have been engaged in framing a Bill which it was hoped might be brought before the consideration of the Government urging reform in the Public Health Department of the Local Government Board. Sir WILLIAM CHURCH quoted three clauses of the proposed Bill; one of which has direct reference to the point in question. The clause runs thus: "That both in the Local Government Board and in the local authorities the medical element should have greater weight and authority than at present and that the medical officers of health throughout the country should be responsible to the Local Government Board as well as to the local authorities." It is the latter part of the clause that should be particularly emphasised. The difficulties which have arisen as to the enforcement of the Vaccination Acts have proved how important it is that there should be a supreme control over the local authorities, especially in regard to medical matters. Unless such a control is enforced constant friction and difficulty will be experienced in carrying out sanitary reforms.

Sir WILLIAM CHURCH impressed upon his hearers the necessity of educating the public on a most vital question and of trying to convince them that efficient sanitation is not a fad on the part of medical men but that it is an essential matter which concerns every living creature. We have frequently laid stress on the necessity of medical practitioners taking advantage of every opportunity of instructing those with whom they come into contact in the elementary principles of preventive medicine. Such tuition, we believe, will have greater force in preventing disease and raising the general health of the people than any by-laws emanating from the local sanitary authorities, although these laws have their use in compelling those who refuse to be taught so to regulate their lives that they may not become sources of danger to their fellow citizens.

Sir John Simon.

THE death of Sir JOHN SIMON is an event of the first importance. Not only does there pass from among us one of the illustrious figures in Victorian medicine, but by our loss of the great pioneer in practical sanitation we are reminded that 60 years ago the most fruitful province of modern scientific research—namely, preventive medicine—was an untilled territory. To appreciate properly the circumstances in which SIMON began his labours in the field of public health requires a conception of times which already seem far back in our history. It is needful to remember that in the "forties" our modern doctrine that it is the duty of the State to seek out and to prevent causes of disease and death among its citizens was seldom advanced or admitted. There was, when SIMON began his life-work, no administrative authority in the country, central or local, that had any medical officer or medical adviser for sanitary purposes; the development of a science and practice of preventive medicine as we know them to-day was quite undreamt of. Of that science and practice SIMON, the first, and for many years the only, medical officer of health in London, and afterwards the head of the medical department of the Government from the year of its creation in 1855 to his retirement in 1876, must be considered as the founder and in some directions the creator. This is made abundantly clear in our detailed obituary which will be found in other columns of this issue of THE LANCET. In his work on "English Sanitary Institutions" SIMON has himself traced many of the circumstances and new movements which by the middle of last century had operated to prepare the public mind to respond in the way that it did to the call for sanitary reform and the prevention of disease. To adopt his phrases, "humanity during the eighteenth and early part of the nineteenth century had slowly become established as an essential and abiding factor in English politics" Underlying the current habits of thought regarding legislation and administration had arisen "a spirit so changed from that of the old times as virtually to be the adoption of new standards of weight and measure in politics" Among the early fruits of this new movement was a recommendation by the Health of Towns Commission that large towns should be given power to appoint medical officers of health The first town to obtain these powers was Liverpool which appointed the late Dr W. H DUNCAN in 1847 The City of London followed in 1848, obtaining Parliamentary powers for the purpose, and SIMON, being then only 32 years of age, held the office from that year to 1855 How the work that he then did led to his appointment as medical officer to the Privy Council, and how his grand conception of his official duties resulted in the formation of a public health service for this country are shown in our obituary notice The record of ability and industry is a marvellous one, and, above all, SIMON'S imaginative faculty must be noted Cultivated to an extraordinary degree, a linguist, a student of Oriental literature, the friend of artists, poets, and philosophers, he was able to think grandly, to project his mind into the future, to discern the real meaning of social evils as well as their probable *developments, and so to devise schemes of prevention and* amelioration that could never have occurred to more plodding if equally industrious spirits This it is to be a man of genius

Annotations.

"Ne quid nimis"

THE WIGHTMAN LECTURE

IN delivering the first Wightman lecture before the Society for the Study of Disease in Children Mr R Clement Lucas after alluding in a few sympathetic words to the circumstances attending the foundation of the lecture, proceeded to discuss the various diseases at one time believed to be constitutional and hereditary and to show what an extraordinary modification of view has taken place in reference to many of these diseases as the result of modern scientific discoveries The position of the majority of the so called diatheses as constituting an etiology behind which inquiry need not be made has been demolished by the discovery of particular organisms which are shown to be the causes of those diseases and which are proved to be infective and communicable from one person to another In this way tubercle, leprosy, malaria, and acute rheumatism have had an entirely new light thrown upon their modes of origin and means of extension, and Mr Lucas makes an interesting quotation from the classic work on medicine written by Sir Thomas Watson to show how the prevailing theory of hereditary transmission caused the best observers to shut their eyes to obvious instances of contagion because "a diathesis is not communicable from person to person" Next in frequency to "diathesis" as a cause of disease heredity was placed in all but the most modern treatises, and here Mr Lucas sums up present knowledge clearly, though his opinions will not escape criticism Passing in review the undoubted hereditary transmission of nervous diseases as well as of mental ability, he alludes to the observations of Langdon Down and Galton as to the relative ability of the children of members of the three learned professions law, medicine, and the church, of which law produces the largest number of distinguished descendants, medicine follows closely, while the descendants of the clerical profession show the largest proportion of weak intellects and the least amount of ability This has been explained by the relative mental activity of the parents and is an uncomplimentary comment upon the Protestant clergy as a whole, founded, some may think, on insufficient grounds With regard to the transmission of external defects and deformities Mr Lucas recalls to our attention with what tenacity such defects as suppressed, supernumerary, and webbed digits cling to certain families in spite of the constant introduction of fresh blood Referring to hare lip and cleft palate he alludes to an observation published by him in the Transactions of the Clinical Society for 1888, showing that the absence of a lateral incisor tooth in a parent may foreshadow a hare lip or cleft palate on the same side in the offspring To this he now adds a further observation that an ill developed lateral incisor in the mother may foretell a more serious defect in the same line of development in her child From these observations it may be concluded that the appearance of a deformity is often not so abrupt as at first sight it would seem to be Dismissing the influence of maternal impressions as unworthy of serious argument, he next shows that many deformities appear to date back to a very early period in the procreative process and it is suggested that an incompatibility between sperm and germ cell, such as produces hybrid deformities in plants, is not an unreasonable hypothesis to account for this fact Later deformities, seeing the number of physical defects associated with the lack of mental development, may be due to lack of controlling influence of the nervous system A defect in development once established is exceedingly difficult to eradicate, for what the lecturer terms the tyranny of the ancestor comes into operation in spite of every desire to escape from his influence Physical and mental deterioration are regarded as dependent on two factors—the defective health of the parents and the unhealthy surroundings and deficient food of the children Much as may be done by good air, food and physical and mental training for the child, he cannot escape from his ancestry and the upward development will be gradual in spite of every desire to hasten it But to this end philanthropy should be directed We regard the lecture as a vigorous attempt to dissipate many medical superstitions that have been impressed by ancient authorities and to bring medical thought up to the level of twentieth century knowledge in matters connected with heredity At the same time we congratulate the society on having been intrusted at this early stage of its existence with a valuable endowed lectureship, and we consider the example set by Mr Wightman of endowing medical lectures as one well worthy of imitation

THE CHILDREN'S COUNTRY HOLIDAYS FUND

WE have repeatedly written in support of this admirable organisation which in many ways has claims upon the public In a few short years the child will become an adult citizen and his good health or ill health will make all the difference between his being a useful or comparatively useless member of society In a recent issue of THE LANCET (July 9th, p 99) we called attention to a letter which Sir William J Collins, the chairman of the Education Committee of the London County Council, had written on behalf of the fund and we have now received an appeal from the Bishop of London, for the subscriptions in hand are nearly £2000 short of the normal amount at this date when there are over 15 000 children booked to be sent to the country for a fortnight's holiday on August 4th As the Bishop of London points out, the schools are standing empty in consequence of the summer recess and until they open again at the end of August

London can hardly contain the hordes of children who pour forth to play in every court and alley, and we agree with his lordship when he says that too many of these children have only exchanged the spacious school buildings for overcrowded rooms. Many children will no doubt have to be disappointed, for some £6000 are required to complete the programme of the committee of the fund, but £2000 are required immediately and we trust that the money will be forthcoming without delay. It is in the interest of the community as a whole no less than in the interest of the individual that we endorse the appeal which is being made on behalf of the fathers and the mothers of the next generation.

ENTERIC FEVER AT ELTHAM AND MOTTINGHAM.

IT is a somewhat remarkable fact that in these days when local government in some places has reached such a high standard of efficiency there should be other places wherein the ratepayers, being unable to obtain satisfaction from those whom they have elected to safeguard their health, should be compelled to call in outside professional assistance, and this notwithstanding the fact that at least one of the sanitary authorities here concerned possesses a medical adviser of distinction and recognised ability. Such, however, appears to have been the case at Eltham and Mottingham, where the repeated occurrence of enteric fever so alarmed certain of the ratepayers that a fund was subscribed and with it the advice of Dr. W. J. R. Simpson, the late medical officer of health of Calcutta, was procured. This fact is instructive in many ways. The inquiry took place at the end of 1903 but we have only quite recently received the report which Dr. Simpson made as to the occurrence. This may have been due to the circumstance that the ratepayers concerned may have been unwilling to draw public attention to the locality until efforts had been made to bring about a better state of affairs. As, however, Dr. Simpson, as a result of a recent visit, is unable to record any very material improvement in the conditions which his first report revealed we presume that the ratepayers are anxious to call to their aid that subtle power known as "public opinion." Dr. Simpson's report, though comprehensive, is a little difficult to follow and in the absence of the necessary information in the report we have had considerable trouble in discovering the sanitary districts involved. We conclude, however, with some hesitation, that Eltham is in the metropolitan borough of Woolwich and Mottingham in the Bromley rural district, and the corresponding sanitary authorities are, according to Dr. Simpson's report, in default. It would appear that in certain areas of these two places, the populations of which are not very clearly indicated, there were cases of enteric fever from 1898 to 1901 and that such cases were distributed in time as follows:—

1898	1899	1900	1901	1902	1903		
6	4	1	5	12	11	=	39

But before dealing with the cases as a whole six are thus eliminated. "The probable cause of one was the partaking of watercress, four were probably imported, and one seems to have been due to the eating of oysters about a fortnight before taking ill." This leaves 33 cases, and three of these formed "part of a small outbreak ...... which Dr. Davies, the medical officer of health, after inquiry, attributed to the milk supplied by a dairy at Eltham." The inquiry into the remaining 30 cases, ten of which occurred in 1902 and ten in 1903, seemed, Dr. Simpson thought, to point to milk as having been the most probable vehicle of infection and there are certainly several facts which are not inconsistent with this view. But we are not told what was the opinion of Dr. S. Davies or the other medical officer of health involved with regard to these cases and the elimination of the nine cases already referred to complicates the matter in one sense while it simplifies it in another. It would, we think, have been well had the milk-supply of all the cases been given. But the facts that 28 of the 30 cases which have been comprehensively dealt with were women or children and that the ten cases in 1902, as also the ten cases in 1903, were all supplied from one source, and that not the source of nearly the whole population, are decidedly suspicious. Neverthelesss, there are some lacunæ which want filling and the age and sex distribution of the population in the special areas involved would have enabled a better idea of the problem to be arrived at. We should, too, have liked a more detailed account of the milk-supply and some information as to whether any of the milk thought to be involved went elsewhere than in the specific rounds of the milkman suspected, whether any of it was sold to other milk vendors and, if so, with what results. The number of cases is so small that most detailed investigation is necessary to furnish adequate evidence for any thesis. Dr. Simpson passes over the water-supply in a somewhat cursory fashion, merely stating that "the water-supply of all the areas is obtained from the Kent Waterworks." It would have been helpful had some further information with regard to the separate mains and hydrants been procured, as the possibility of local contamination in a polluted soil such as this was shown to be has to be borne in mind. But the outbreak does not look to us quite like a water-borne outbreak and in the absence of a definite common cause more information with respect to the possibility of personal infection would have been of value. But whatever may have been the cause of the Eltham and Mottingham cases Dr. Simpson's inquiry has undoubtedly revealed the fact that the sanitary condition of the dairy farms from which the milk of the district was procured and the cleanliness of the cattle from which the milk was drawn were far from satisfactory. Moreover, there are certain facts which suggest that the udders and the legs of the cows may have become specifically fouled from the streams in which the cattle waded. If, therefore, the inquiry had led to improvements in this direction gratitude would be due to the ratepayers who have found the money for the inquiry. But, as is so frequently the case in circumstances such as these, no such improvement appears to be taking place in spite of the fact that Dr. Simpson has pointed out several matters which require rectification. Unfortunately the report contains but little reference to the powers under which these improvements might be made. For instance, we are still in ignorance as to whether the Bromley rural district council has made any regulations under the Dairies, Cowsheds, and Milkshops Order or whether any action has been taken under the Rivers Pollution Prevention Acts. It is always well to put before the local authorities the machinery by which the reforms suggested may be carried out. Unofficial inquiries of this nature are somewhat delicate proceedings and the relations of the medical man concerned with the officers of the local authority are apt to be difficult. But in cases where the local officers have advised their local authorities in vain, and the aid of the Local Government Board cannot be procured, the advice of an expert well trained in epidemiology and administrative methods may not be unwelcome. But the occasions must necessarily be rare.

THE ETIOLOGY AND TREATMENT OF ARTERIO-SCLEROSIS.

IN accordance with the wider growth of knowledge concerning arterio-sclerosis as a cause of disease and premature decay increased attention has been given in recent years to the early diagnosis and treatment of this morbid constitutional condition In THE LANCET[1] some months ago an account was published of the early diagnosis of arterio sclerosis In a recent discussion at the New York Academy of Medicine, a report of which is published in *American Medicine* of June 25th Professor J M Anders of Philadelphia and others dealt with the no less important matters of the etiology and treatment of arterio sclerosis Professor Anders divides the causes of arterio sclerosis into five categories first, toxic agencies such as syphilis, alcohol, and gout secondly over eating (excess of carbohydrate and nitrogenous food) thirdly, constant hypertension of the arteries produced by muscular overstrain as in some forms of athletics fourthly, aortic regurgitation, and, lastly the oncoming of senility (senile degeneration) Prophylaxis should, he says be begun in early life when a tendency to arterio-sclerosis is detected The diet should be carefully regulated over eating should be avoided, and the amount of nitrogenous matter (meat) consumed should be reduced to as little as possible Athletics involving much muscular exertion such as rowing wrestling, and weight-lifting, should not be indulged in, a little walking and daily massage being found sufficient to keep up the tone of the muscles Water, says Professor Anders, may be freely drunk, so as to promote perspiration and the free excretion of waste products by the kidneys Young men should be urged to moderation in games or feats of endurance Arterio sclerosis is not arrested but may be retarded by drugs especially the alkaline iodides nitro glycerine, and the nitrites, all of which tend to lower the excessive arterial tension which marks the oncoming of arterio sclerosis In the discussion which followed the above communication Professor Alfred Stengel of Philadelphia stated that for successful treatment the disease should be taken in hand before nephritis or angina pectoris has developed He has known arterio sclerosis to follow convalescence from infectious fevers, especially typhoid fever He urged that in all cases of convalescence from severe infectious fevers the period of rest and of abstention from work should be extended over several months during which a steady course of tonic treatment should be pursued before the patient is permitted to engage in active or arduous work Dr F Shattuck of Boston stated that alcohol should be absolutely forbidden to persons suffering from incipient arterio sclerosis, as indulgence in it, even to the slightest degree, aided the rapid development of the disease Dr C Stockton of Buffalo said that in addition to strict abstinence from alcohol, a careful and light diet, and the administration of iodides and nitro glycerine in small doses and for prolonged periods, the patient should be given vapour baths twice weekly Dr A Jacobi of New York spoke of the danger of cardiac lesions (dilatation and cardiac insufficiency) which could be obviated by attention to details of diet and exercise and the administration of suitable drugs Cases due to syphilis required careful and mild but prolonged antisyphilitic treatment

CANAL ANGLERS

IT is perhaps doubtful whether the attraction of angling in the canals with worm or other bait is as keenly felt in the south of England as it is in the north There are in the northern towns thousands of working men who will sit patiently hour after hour watching their floats, at the end of which time they may not be able to boast that they have even had "a glorious nibble" On the Saturday before last 700 such men sat at fixed distances for a length of four miles on the banks of the Macclesfield canal for nearly two hours They had time to smoke and to think, to bear out, indeed, Izaak Walton's statement that angling is the "contemplative man's recreation" 500 of them are said to have caught nothing The heaviest fish was just over eight ounces and the smallest, as the report puts it, "was a ponderous creature of two drams" At all events, it is a harmless amusement and affords to its devotees the opportunity of breathing comparatively pure air

THE PRESERVATION OF CHILD LIFE IN NEW ZEALAND

THROUGH the courtesy of the Agent General for New Zealand we have been furnished with a memorandum by the Premier of that colony on the preservation of child life Briefly stated the object of this publication is to assist the introduction into New Zealand by a special Act, of a widespread system of charitable relief in relation to the dangers, necessities and illnesses of childhood Under the provisions of this Bill no midwives will be allowed to practise who are not duly qualified and their registration will be insisted on A certain number of these certified women will be appointed in each district to attend poor persons gratuitously, their fees being paid out of the public funds Maternity homes will be established and maintained throughout the colony Hospitals will be erected and maintained expressly for the children of the poor A staff of trained nurses will be provided for gratuitous home attendance Day homes or crèches will be established for the reception of young children whose mothers are obliged to go out to work The expenses necessarily connected with these various undertakings will be paid by the State Further enactments resembling those in force in the mother country will be concerned with the prevention of cruelty to children Abuses arising from the insurance of young children will be controlled if not prevented, by limiting the amount to be insured in the case of any child under ten years of age to a sum not exceeding £5 The maintenance of illegitimate offspring will be secured in an equally practical way by compelling the guardian, mother, or alleged father to register the child—even a single child, be it noted—and by refusing the power to commute weekly or monthly payments with a capital sum It is impossible not to sympathise with the intention of those who have designed this plan of charity Certain of its clauses will meet with universal approval All are worthy of notice as indications of an honest endeavour to solve a social problem than which there is none more worthy the attention of any people—the well being of its children We admit the obligation in many cases to assist poor persons with medical service and nursing at the public expense We entirely concur in the resolution to put down cruelty after the methods which have proved so successful and so little irritating in this country We congratulate those who have gone a step further than ourselves to regulate the insurance of young children and to save the illegitimate from the cruelest subtleties of infanticide Having admitted so much it seems almost ungracious to resort to adverse criticism of details but too much help must not be proferred to people who can help themselves The so-called poor in New Zealand where the working classes are in a relatively prosperous condition, can do much to help themselves It would be an occasion of lasting regret and a cause of public damage if the principles of self help and parental responsibility—factors in the creation of a sturdy type of character to which our race is deeply indebted—were swamped, as there is some prospect of their being by the gratuitous generosity which the memorandum seems to contemplate Where there is destitution the case is different Here necessity calls for free service as an indispensable and for the most part as a temporary act of grace The poor man who can contribute somewhat towards the cost of treatment in illness, his own or that of others dependent on him, business, and the other is that all persons employed in slaughter-houses should be licensed. The need for the adoption of the first of these recommendations has long been insisted upon in our columns in the interest of man, and the other is one which will equally commend itself to those who have sympathy with the lower animals. We shall view with much satisfaction any efforts which are made by the lovers of animals to insure effect being given to the recommendations of the committee, which are evidently based upon careful observation and upon common sense.

---

[1] THE LANCET, Jan 30th, 1904, p 316.

THE CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH.

(FROM SPECIAL CORRESPONDENTS.)

THE annual meeting of the Royal Institute of Public Health was this year held at Folkestone from July 21st to 26th, under the presidency of the Earl of RADNOR.

THE OPENING MEETING.

The first meeting on July 21st was held in the Pleasure Gardens Theatre, the proceedings being opened by the Mayor of Folkestone, Councillor GEORGE PEDEN, J.P., who welcomed the delegates and members.

Dr. WILLIAM R. SMITH (London), as President of the Royal Institute of Public Health, gave an account of the mission undertaken by that organisation. It endeavoured to spread the gospel of cleanliness among the poor and among the better classes. The children were of the greatest importance to the community and in this respect he believed that the Midwives Act would prove of great benefit. Every district also should have its nurse and the children should be trained in, and taught, the habits of health. He thought that in dealing with public health questions much could be done to unite more closely the colonies with the mother country and they proposed to create branches of the institute in the colonies. At the conclusion of his speech Dr. SMITH installed the Earl of Radnor as president of the congress.

The Earl of RADNOR replied, expressed his gratification, and alluded to the useful work of the congress. He spoke more especially of the question of milk-supply, on which so much depended, and insisted that this necessitated the spread of the principles of hygiene in rural districts where the milk was contaminated in the cans washed with the impure water of small wells. Indeed, the whole speech was a plea for more sanitation in the country districts that fed the great towns.

In the afternoon the real business of the congress began and the sections met at the Technical Schools. The business of the congress was conducted in five sections: (A) Preventive Medicine; (B) Bacteriology and Chemistry; (C) Engineering and Building Construction; (D) Child Study and School Hygiene; (E) Ladies' Section; and (F) (*a*) Tropical Medicine, and (*b*) Physical Training. In all valuable and instructive papers were read and discussed and the attendance in the Preventive Medicine and Child Study Sections was especially good.

SECTION OF TROPICAL MEDICINE.

Dr. W. J. SIMPSON, professor of hygiene in King's College, London, presided over this section and took for the subject of his address

Preventive Work in the Tropics.

He pointed out that sanitary measures, irrespective of the microscope and the laboratory, had achieved great triumphs. In the West Indies the lifetime of a regiment 1000 strong used to be estimated at about five years. This mortality, first ascribed to the climate, was shown to be due to removable causes and by improving the food-supply and water-supply and remedying the overcrowding a very different condition of things was brought about. In India the death-rate of the soldier had fallen from 80 to 16 per 1000. Dr. Simpson then detailed the great discoveries that had been made in tropical medicine in recent years, in cholera, plague, and Malta fever, in malaria, yellow fever, and sleeping sickness, and discussed the measures that were being taken and the results obtained in the campaign against malaria. Speaking of the Haffkine prophylactic against plague he said he doubted whether a fluid that had to be inoculated would ever be largely used on account of prejudice against this mode of administration and advocated experiment in the direction of finding something that would be efficacious when taken by the mouth.

As a result of the discussion that followed the section adopted this motion:—

> That this section of Tropical Medicine recommend the council of the Royal Institute of Public Health that it is desirable to approach the Secretary of State for India and Lord Curzon and lay before them the importance of a largely increased special sanitary service for India.

By request Mr. JAMES CANTLIE (London) then gave an address on

Beri-beri.

At considerable length he described the geographical distribution and treatment of beri-beri, following this up by giving the signs, symptoms, and alleged causes of the disease. In the past no attention had been paid to beri-beri but at the present time a dozen cases could be produced in London. It was peculiar how diseases became fashionable; beri-beri seemed to be fashionable to-day. People who had money invested in South Africa seemed to be paying much attention to beri-beri now and it was a good thing for the Empire, he declared, that at last they had taken notice of one of its greatest scourges. He explained the different types of the disease and mentioned places where beri-beri had largely existed, though under other names.

Dr. ALEXANDER CROMBIE (London) followed with a paper on

The Frequency and Causes of Atonic Dilatation of the Stomach in the Tropics.

This he ascribed especially to the habit of over-drinking at meals, some 50 per cent. of the cases being attributable to this cause alone. As an instance he said that at dinner many men thought nothing of taking half a pint of soup, two pints of aerated water during an otherwise ample dinner, and another pint or two pints of the same within the next one and a half hours. A similar distension of the stomach was practised, to a less degree perhaps, at breakfast and lunch, with the result that the organ in the course of a few years of such treatment accommodated its mechanical capacity to the demand made upon it. Digestion was at the same time delayed by this inordinate dilution of the gastric juice and sooner or later the stomach failed to empty itself before it was again deluged in a similar manner. Other causes were typhoid fever and neurasthenia.

SECTION OF PREVENTIVE MEDICINE.

Dr. W. J. TYSON, senior physician to the Victoria Hospital, Folkestone, presided over this section.

He was followed by Mrs. GARRETT ANDERSON, M.D. (London), who read a most instructive paper on

The Economic Value of Compulsory Vaccination at School Age.

She contended that it would be much cheaper to revaccinate than to maintain small-pox isolation hospitals. In Germany there were no small-pox hospitals. At Berlin in the ordinary hospital 12 beds were reserved for the few imported or chance cases of small-pox that might occur and this was for a population nearly half that of London. The British metropolis, counting the capital outlay, spent £30,000 a year for the isolation of cases of small-pox and the average of five years showed that they had only six patients per day to nurse. Unfortunately, and instead of continuing this discussion on the relative cost of isolation and of revaccination, a Mr. ROSE of Sandwich rose to denounce vaccination as "the greatest of frauds" and indulged in violent abuse. This caused other speakers to treat the general question of vaccination instead of the special phase which Mrs. Garrett Anderson had introduced.

Remarks by the President.

Friday morning was devoted to a very interesting discussion on milk preceded by the opening address from the PRESIDENT of the section. He pointed out that by the drainage of some marsh lands Folkestone had been entirely freed from the presence of ague. Much had also been done to reduce the frequency of tuberculosis, but, on the other hand, such a state of things as existed at Sandgate should be rendered impossible. There were present constantly some 300 phthisical patients living in the midst of a population of 2000 inhabitants and this in houses where little or no control was exercised over them. It was a grievance which the section would have to discuss. Then he alluded to the great epidemic of typhoid fever at Maidstone and to the fact that though much had been done in the surgical treatment of the wounded during the Boer war, a great number of soldiers died from typhoid fever and no serious attempt had been made to provide pure water during the campaign In regard to cancer, he thought that this disease was treated at the wrong end and that better results would accrue from preventive measures The infantile mortality was still equal to 1 in 7 within the first year of life To this the milk question was closely allied and the purity of milk depended upon farmers and dairymen who were not properly controlled by the rural sanitary authorities To boil and to sterilise milk not only tended to destroy its anti scorbutic properties but it gave an excuse to the farmers for their carelessness Finally, the President lamented, in the constitution of school authorities, the absence of technicians in regard to physical education For such purposes we should possess a Minister of Public Health

Dr J T C NASH, medical officer of health of Southend, introduced a discussion on

A Clean Milk supply

He said [illegible] came to [illegible] from the [illegible] a slight acquaintance with sanitary precepts must wonder at the marvellous natural protective powers of the human economy The cowshed in the country more often than not was an old wooden structure or barn insufficiently lighted and ventilated, [illegible] imperfect means of drain[illegible] lacking in every principle [illegible] the farmer and the cowman [illegible] production of clean milk supplies The public should know that it was possible to secure clean, wholesome milk and should insist and assist in every possible way in securing it It became necessary to insure systematic methods of cleanliness and expedition in the storage, transit, and distribution of milk The normal temperature of milk as drawn from *the body of the cow was extremely favourable to the rapid* growth of bacteria Therefore it was important to prevent the introduction of further extraneous germs by keeping the milk covered and to arrest the multiplication of existing germs by cooling the milk as soon as possible after it was drawn by passing it through a clean refrigerator or by storing it in an ice cellar No cowshed should be permitted to continue without a refrigerating apparatus in a separate building within easy access of the cowshed, so that the milk could be cooled down to a temperature of 50° F at once The conditions which at present prevailed as to the transit of milk by rail were in need of reform Special ice vans should be a *sine qua non* The importance of covering milk in order to prevent contamination by flies and dust had, perhaps, hardly been sufficiently realised heretofore Recently the Southend town council had passed a regulation under Article 13 of the Dairies, Cowsheds, and Milkshops Order of 1885, which had been approved by the Local Government Board and read as follows —

> Every retail purveyor of milk shall cause every vessel containing milk to be protected from dust flies and other *sources of contamination* by means of suitable covers

The Distribution and Sale of Humanised and Sterilised Milk

was the title of a paper by Mr Councillor SHELMERDINE (Liverpool) He gave an account of the municipal milk depôt in that city and its administration and the details of preparing and distributing the milk As regarded the results he said that without attempting to draw too close deductions the fact stood out that of the 4453 infants coming very promiscuously to the depots at varied ages and in conditions of health below the average the mortality was 78 per 1000 as against 159 per 1000 for the whole city But it must be remembered that in that 159 per 1000 for the whole city and 88 to 118 for the best districts, and 212 to 215 for the worst districts, were included also breast-fed infants, clearly if breast fed infants were excluded and artificially-fed infants only taken into account the rate of mortality amongst them would be enormously higher, and would show even more forcibly the advantages of the sterilised food which, of course, is an artificial food, over *other methods of artificial feeding*

Mr J PEARSON sanitary inspector of Folkestone, read a paper containing the most alarming description of an individual who for more than two years was employed to milk cows in several different towns and farms of Kent Wherever he went cases of typhoid fever occurred among those who drank the milk of the cows which he tended. Incredible as this may seem, the names and the fullest details were given and typhoid fever only ceased when the man having thus injured his own son's business was persuaded *to give up altogether his occupation of tending* and milking cows Mr Pearson thought that the rural authorities were composed so largely of farmers that nothing would be done unless some higher authority was brought to bear

Mr E J BISHOP read a paper describing a process of [illegible]

[illegible] As a rule they were anxious and eager for advice and wished to do the best for their children The town of Liverpool had done a good work but at a financial loss, for it had incurred in 1900 a deficit of £6310 to provide milk for 6295 children Also, there was the question of rickets and so on attributable to sterilised milk At best it was but a partial success The true solution, he maintained, rested in the municipalisation of the milk supply Taking the dairymen's own estimate that the goodwill of a cow was worth £10 and the cows £20 each for the 60 000 inhabitants of the borough of Bootle this would make a total for the purchase of the present animals of £12 960 A great economy in the dis*tribution of milk would be effected There would no longer* be three or four rival distributors in each street and even if they sold the milk at 1*s* instead of 1*s* 3*d* per gallon they would receive at least £34 127 a year The sale of manure would raise this income to £36 627 The annual expenditure would be £22,466 leaving £14,161 to pay interest on capital, depreciation, and the like The net profit would be considerable but the real benefit held in view was that of exercising absolute control over the milk supply They might therefore hope to be able to guarantee its purity

In the discussion which followed Dr E W HOPE (Liverpool) admitted the loss but said that they put health before cost

Mr WILLIAM HALL (Headingley, Leeds) said that he had examined 2000 poor Jewish children, dirty slum dwellers, and said that they were far healthier than Christian children living under better sanitary conditions This was due simply to the fact that they were better fed—namely, from their mother's breasts and not from the bottle

Sir CHARLES CAMERON insisted that the country dairies were much worse than those of the towns

Professor M HAY (Aberdeen) wanted owners of dairies to obtain sanitary certificates which would be of use to them commercially while affording some security to the public

The general sense of the section was in favour of compulsory inspection organised by a superior authority which could not be influenced by local interests

The Adulteration of Milk

was the subject of a paper by the Rev Canon HORSLEY, chairman of the public health committee, Southwark He dealt with the statistics of adulteration in various towns and concluded that in order to encourage the honest and to discourage the dishonest traders at least four samples should be examined yearly *from every* dealer

In the afternoon Dr C KILLICK MILLARD, medical officer of health of Leicester, caused some excitement by reading a paper on

The Utility or Otherwise of Isolation Hospitals

Considerable misapprehension existed and it took some *time to dispel false impressions* Dr Millard did not challenge the use of such hospitals but urged that there had been some abuse in regard to one single disease—namely, scarlet fever Nor did he mean that no case of scarlet fever should be sent to an isolation hospital He was in favour of isolation but thought isolation at home was preferable when it could be practised He gave a number of figures to show that where this had been done the results were quite as good and were attended with less risk to the patient He therefore advocated an inquiry into the matter and proposed the following motion —

> That as the hospital isolation of scarlet fever has now been tried on a [illegible] a doubt exists as to whether the [illegible] the cost, it is desirable, in the [illegible]itative inquiry into the subject [illegible]

This was seconded by Dr A M FRASER (Portsmouth) in a brief speech

Mr T W N BARLOW (Bootle) said that, to his mind, the crux of the whole question lay in the possibility and efficiency of home isolation and that in towns where home isolation could not be depended upon fever hospitals were indispensable and without them scarlet fever would run riot much as measles did at present.

Mr. H. BEALE COLLINS (Kingston) supported Dr. Millard's view. He said that in Kingston, a town of suburban villas, home isolation could be efficiently carried out as a rule and that it was not necessary to remove more than 7 per cent. of the cases to the hospital.

Dr. KENWOOD dissented from Dr. Millard's views. Perhaps too many cases were now removed to hospital but he regarded hospitals as valuable not only for isolation but also from the point of view of treatment alone.

Dr. SIMPSON said that he had attacked isolation hospitals and their administration but not isolation. He regarded the cubicle system as it obtained in Paris as the ideal one.

On a show of hands the motion was declared carried by 33 votes to 20.

SECTION OF BACTERIOLOGY.

Professor KLEIN, the President, opened the proceedings with an address on

The Aim and Scope of the Bacteriological Analysis of Water and of Shell-fish with reference to Sewage Pollution.

He dealt with the methods, data obtained, and their significance and severely criticised the methods and reports of the metropolitan water examiners.

Dr. R. T. HEWLETT (London) then presented the report of a committee appointed at the last congress to inquire into the standardisation of methods to be employed in the bacterioscopic examination of water. A committee of representative bacteriologists had carefully considered the subject and had drawn up a scheme which, if adopted, would conduce to a systematic and uniform procedure. On the motion of Dr. Hewlett it was resolved that a copy of the report should be forwarded to the Water Board of London.

Mr. A. G. R. FOULERTON (London) then read a paper on

The Pollution of Tidal Waters by Sewage.

It was a lengthy contribution abounding in analytical and statistical data and an important contribution to the subject. It was briefly discussed by Dr. SAVAGE and the PRESIDENT.

SECTION OF CHILD STUDY AND SCHOOL HYGIENE.

Sir GEORGE KEKEWICH, K.C.B., presided over this section and gave an address on

The Physical Education of Our Children.

He said the subject comprised not merely physical exercises and physical training but the conditions under which children lived both at school and at home. With regard to the schools the Board of Education had not done, and was not now doing, its duty in regard to seeing that suitable buildings were provided. Tenderness for the pockets of the owners of schools meant cruelty to the children. With regard to the expenditure, although there might be no return in actual coin of the realm, it would be a good outlay, inasmuch as the poorhouses and hospitals would be less crowded.

The Teeth of Children in Relation to Public Health

was the subject of a most interesting paper by Mr. J. G. TURNER.

Dr. HARRY CAMPBELL (London) discussed

The Evil Effects of Too Soft a Diet in Children.

He advocated "that the child should begin to take hard solid foods at the seventh month, when he should be allowed to gnaw at chop bones and chicken bones and to eat hard leathery crusts, biscuits, sugar cane, and certain fruits. In this way the instinct to masticate is afforded due opportunity to develop; when the child has learnt to masticate by instinct, and not till then, a limited quantity of the softer farinaceous foods may be permitted."

Dr. T. WHITEHEAD REID (Canterbury) read a suggestive paper on School Food, advocating greater variety and directing attention to the value of chestnuts, banana and wholemeal flours, tripe, vegetable soups, and the like.

LADIES' SECTION.

This section met at the Woodward Institute under the chairmanship of the Countess of RADNOR (the President). Some of the subjects discussed in this section were the appointment of ladies as sanitary inspectors at the same rate of payment as the male officers; a paper on Domestic Hygiene by Dr. CLARA FITTER; Invalid Children's Aid, by Miss MUNNS; and Children's Emigration, by Mrs. CLOSE.

Lady HAMILTON proposed the following motion:—

> That the council of the Royal Institute of Public Health be earnestly requested to take into consideration the desirability of steps being at once taken, either through the agency of the municipal corporations or by some other means, of bringing home to the poor a knowledge of the principles of health.

This was seconded and carried.

Councillor HUNT (Acton) read a paper on

Municipal Crèches

and moved—

> That this meeting is of opinion that municipal authorities should be empowered to erect and maintain day nurseries for the care of the infants and young children of women employed in day labour, and that for such purpose the Government be petitioned to introduce an adoptive Bill in the next session; that copies of this resolution and Mr. Hunt's papers be sent to the Prime Minister and also to each municipal and local authority with a request to their respective Parliamentary representative to support the Bill.

Councillor BROADBENT (Huddersfield) seconded the motion which was carried.

Excursions.

Saturday was devoted to excursions. Some members of the congress went to Dover, others to Canterbury, but the majority crossed over to Boulogne-sur-Mer. The turbine steamer *The Queen* had been secured for that purpose but as the channel was perfectly smooth there was no opportunity of testing the sea qualities of this magnificent ship. The splendid weather, however, contributed largely to the enjoyment of the trip. The Mayor of Boulogne was awaiting the arrival of the ship on the quay together with a band to play the national anthems of both countries and a large crowd received the visitors with cheers. Lunch and toasts at the Casino further cemented the bonds of amity between the two countries and the two towns which face each other across the Channel. The municipality of Boulogne offered tea to the visitors at the Hôtel du Nord prior to their departure and altogether a most enjoyable day was experienced by the 360 excursionists who availed themselves of this opportunity.

SECTION OF PREVENTIVE MEDICINE.

The Debate on Sanatoriums for Pulmonary Tuberculosis and the Sandgate Scandal.

On Monday Dr. NATHAN RAW (Liverpool) read a paper introducing the question of Sanatoriums for Consumptives. He insisted on the necessity of organised effort being made by public bodies, such as municipalities, county councils, boards of guardians, and others, so that such institutions might be created. They had an excellent educational effect but the treatment "must be carried out under the direct supervision of a medical man specially trained for this special work." He then insisted on the selection of a suitable site on a high altitude and well away from smoke and other impurities. The incapacity to work caused by phthisis cost London over £4,000,000 per annum and he had calculated that the working classes of Liverpool lost annually in wages through being invalided by this disease at least £300,000. But in Germany much of this loss had been saved owing to the fact that from 68 to 74 per cent. out of 27,176 patients treated in sanatoriums had been able to return to work. He thought that the health authorities had ample power under the Public Health Act to deal with consumption and the county councils could also proceed in the matter under the Isolation Hospitals Acts. In conclusion, he denounced the present practice of calling anything a sanatorium. This led to disappointment, because the results in unsuitable places were not encouraging and the public had been led to expect too much from sanatoriums. Nevertheless, they constituted the best treatment medical science could offer to-day, though they could only be successful in selected cases.

Mr. ADOLPHE SMITH was invited to speak next. He said that they had close to them, at Sandgate, so-called sanatoriums for the treatment of tuberculous disease which in no wise answered to the description given by the opening paper. Dr. Raw claimed that such sanatoriums should be managed by medical specialists but at Sandgate no medical man was responsible. The British law sought to prevent the people from resorting to quacks. British boards of guardians, in carrying out the Poor-law, sent patients to the homes at Sandgate which were managed by absolutely unqualified persons. The Jones's homes at Sandgate professed to give outdoor treatment but it was out-in-the-street treatment, where the pure air consisted of the maximum supply of motor-car dust. In Germany extensive experience showed that sanatoriums cost £200 per bed and more than

4s per day per patient, altogether and all told from £90 to £100 a year At Sandgate only a guinea a week was paid and out of this a profit was made The speaker strongly denounced the running of such enterprises for profit and the trading on the miseries of the poor

Mr L J D **BROCKMAN** speaking as a lawyer living at Sandgate, explained that nothing could be done till medical science had spoken It was necessary that tuberculosis should be defined as a dangerous and notifiable disease They could not deal with the internal arrangements of a house unless the nuisance therein created became an external nuisance But if tuberculosis could be qualified and recognised as infectious they would have a right of entry, of removal of patient of disinfection and of isolation But even then it would be necessary to define what was a hospital, for the Act did not apply to hospitals

Dr C E **PERRY** medical officer of health of Sandgate now rose first to express his thanks to THE LANCET for all that journal had done to help them to get rid of a serious grievance The utility of sanatoriums depended on their management and he knew personally several cases where great benefit had resulted But this was due to the situation of the sanatoriums and the excellence of their management At Sandgate the Jones s homes were in the main street, they had no gardens and the patients mingled with the general population On the Riviera the general population had suffered from the presence of such phthisical patients who went to winter in the south Now the hotels refused to receive people suffering from tuberculosis and they were sent to a splendid [illegible] on the hills behind Mentone [illegible] wrong to run homes for priv[illegible] should be constructed by the public authorities and paid for out of the poor rates

Mr S **BACON** town councillor, from Poplar agreed that the homes at Sandgate where some of the poor from Poplar had been sent were unsuitable for the purpose but the London guardians did not know where to find suitable homes Some time ago the guardians held a meeting at St Martin s Hall to discuss what measures could be taken for the metropolis in this matter They received expressions of sympathy from all sides but nothing was done, so they remained with no choice but Sandgate or the workhouse The difficulty was to treat London bread winners in the early state of the disease They naturally would not leave off work to go to a workhouse and be pauperised but there would be less objection to go to a hospital or a sanatorium where there would be no degrading conditions

Dr **MILLARD** said that at Leicester they used a ward of their fever hospital, which had 20 beds for the treatment of tuberculosis

Dr **BARLOW** questioned the usefulness of sanatoriums for tuberculosis and Canon **HORSLEY** said that at Southwark they had left off sending their cases to Sandgate and this now for several years Nothing effective would be done unless there were compulsory powers and the poor would only believe that the disease was dangerous when they saw disinfection enforced But even if a man was sent to a sanatorium he would soon fall ill again when he went back to his wretched home General hygiene would do more than special sanatoriums

Dr W F **DEARDEN** (Manchester) said that to send patients to Sandgate was no better than to leap from the frying pan into the fire People would go to a good hospital but not to a workhouse infirmary At Manchester they were subsidising by retaining and paying for a certain number of beds a large hospital that was in course of construction outside the town This would constitute a sort of municipal sanatorium

Councillor B **HOBBIS** Mayor of Maidenhead alluded to the action of the great friendly societies They had sent a deputation to Germany which reported favourably in regard to the sanatoriums for the treatment of phthisis Nevertheless the friendly societies had not moved in the matter If the truth must be told it was not in their interest that sick members should live long Those members who returned from sanatoriums patched up but disposed to fall ill again cost too dear The friendly societies contented themselves with dealing with this matter as they had dealt with the question of old age pensions—they handed over the problem to the State

Dr J C **MCWALTER** (Dublin) said that the question had been much discussed in Ireland and the feeling was that sanatoriums for tuberculosis were considered to be too expensive as their results were of doubtful benefit They produced apparent cures but the patient soon relapsed when he returned to slum life Where better results were shown it was because patients had been taken at such an early stage that in ordinary circumstances they would hardly have been considered as invalids

Dr G **HOLLIES** insisted that if the patient had a suitable home as much could be done for him in his own dwelling as in a sanatorium

Dr J **WRIGHT MASON** (Hull) inquired who was to supply the sanatoriums He thought that this should be done by the municipalities but he was opposed to palatial buildings and great expenditure If outdoor treatment was required then nothing was better than tents and they did not cost much

Dr **RAW** in his reply regretted that the question of the homes at Sandgate had been introduced He knew nothing about them and could not therefore deal with that phase of the subject What he wanted to bring forward was the fact that pulmonary tuberculosis was infectious and was curable and that sanatoriums constituted the best means of effecting such cures As for the question of expense under the Poor law and solely for the treatment of phthisis £1 000 000 were now being spent annually Surely it would be better to devote this money to sanatoriums even if they only restored the patients to their work for two or three years

Dr **PERRY** rose at the conclusion of the reply to suggest that some motion summarising the opinions expressed should be submitted before passing on to another subject

Mr **ADOLPHE SMITH** thereupon moved the following —

> [illegible] e aggregation and treatment of [illegible] heir own groups in an isolated [illegible] ilation and be placed under the [illegible] cal practitioners

Dr **PERRY** seconded this motion

Mr **BACON** objected He did not see the need of such a motion, it tied people s hands and therefore he moved the previous question

No one however could be found to second the previous question so the motion was put and carried by a large majority This brought the debate to its logical conclusion

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND

THE annual meeting of this association was held in London on July 21st and 22nd The presidential address was delivered by Dr R **PERCY SMITH** who chose for his subject Paranoia its position as a clinical entity and its relationship to other mental disorders Paranoia as a term to describe a certain primary cause of insanity was first used by Kahlbaum in 1874 and since then by Mendel (1881) Spitzka (1887), and others The death in 1886 of *King Ludwig II* of *Bavaria*, who was a life long victim of this form of mental disorder, served to draw increased attention to the study of paranoia. The medical certificate of death signed by four specialists in mental disease referred to the king as having suffered from that form of mental disease which is well known to alienists and physicians of experience as paranoia The term ' paranoia had however, though largely and widely employed by alienists in Europe and America received scant attention in Great Britain no mention being made of it in the writings of *alienists of the older school* *Thus, it was* not mentioned in the text books of Savage (1884) or Bevan Lewis (1889) Clouston (1892) referred to it in a brief paragraph in the third edition of his work and the late Dr Hack Tuke gave an account of paranoia in the *Dictionary of Psychological Medicine* (1892) At first some confusion prevailed in the use of the term, since some authors did not discriminate between this grave constitutional, progressive chronic disease of the mind and other acute mental disturbances which only superficially resembled it but had nothing in common with it as regards fundamental characters and mode of evolution of symptoms Thus in addition to the original paranoia (the *primare Verrucktheit* of German authors and the *délire chronique à évolution systématique* of French writers) which was a chronic and incurable disease running a definite course of several years' duration a motley group of acute affections classed together under the term "acute paranoia" was included under paranoia by various writers, with the result that instead of clearness and discrimination much confusion had resulted. In the last decade, however, mainly owing to the work and writings of Krafft-Ebing, Magnan, Kraepelin, and others, and the growth of a broader and essentially different standpoint adopted in the investigation and classification of the insanities from the evolutionary and prognostic aspects, the conception of paranoia had grown clearer and its position in the scheme of the insanities was better defined. Cramer, who a few years ago summarised the history of the subject, pointed out the essential unity of the modern view of paranoia as developed by Magnan and Kraepelin. He referred but little to English writers and evidently was inclined to regard their views as obsolete. He said that Italian investigators had either followed the French or the German school, which remark might be applied to the younger rising school of psychiatry in the United States. Dr. Smith then dealt with the question, long debated by alienists, as to whether paranoia in the proper sense (i.e., excluding the so-called acute paranoia, a term which was fast dying out) was primarily a disorder of the affective side of mind (the sphere of feeling and emotion) or of the intellectual process and after a lengthy survey of the facts and arguments available came to the conclusion that the former view of its pathogenesis must be considered the correct one. Krafft-Ebing in the latest (1903) edition of his "Lehrbuch" classified paranoia under the subdivision Psychical Degenerations (which included katatonia, *folie raisonnante*, paranoia, and periodic insanity), as distinguished from the psycho-neuroses (which included melancholia, mania, primary (curable) dementia, hallucinatory delirium, and the secondary delusional and terminal dementias). Kraepelin had recently described a paranoid form of dementia præcox, a somewhat rare variety of the insanity of adolescents, presenting a superficial resemblance to paranoia but nevertheless essentially distinct therefrom. Dr. Smith concluded by stating his own view that paranoia was a chronic insanity marked by a stage of systematised delusions, whether of persecution or of exaltation variously combined, that it originated in youth, adolescence, or early adult life, and was more or less associated with a basis of heredity (neuropathic or psychopathic), that the disturbance of the mind was *abinitio* probably in the affective sphere, and that it was etiologically and clinically different and distinct from acute states of delirium and mental confusion or collapse-delirium, and from secondary states of fixed delusions occurring after attacks of acute insanities.

Dr. G. E. SHUTTLEWORTH read a paper on the Educational Treatment of Young Epileptics. He referred to the passing of the Act of 1898 for the education of epileptic children which enabled the local authorities to provide farm colonies and schools for the care, training, and treatment of young epileptic children. In institutions such children could be brought up in a life of relative usefulness and by the provision of workshops and the teaching of handicrafts to the inmates (such as knitting, needlework, fretwork, basket-making, and farming) the institution could be rendered in a measure self-supporting. He adduced the epileptic colony at Chalfont St. Peter, Bucks, as a typical example. Other institutions were also in course of erection or had been recently completed and opened for the reception of patients at Much Hadham (Herts) and in Cheshire. He was of opinion that accommodation for about 3000 inmates was required for this class of cases in England, while the existing institutions did not provide for more than about 400. The education given in the schools and classes attached to these institutions included physical drill and games involving moderate muscular exercise. Idleness was as bad for the epileptic as for the healthy child. Epilepsy *per se* did not, and in his opinion should not, disqualify a child from the benefits of elementary education. He was strongly of opinion that a physician should be called in to examine and to certify a child suffering from epilepsy as to whether the child was a suitable subject for school or farm colony education and training. Class teaching was better for epileptic children than solitary instruction and corporal punishment should never be administered. Games in the open air were of great benefit to epileptics. Dieting and a proper regulation of the bowels were important matters and the judicious use of some doses of alkaline bromides was often attended with benefit.—In the discussion following the above communication Dr. G. H. SAVAGE stated that medical supervision and dietetic and medicinal treatment in the form referred to above should be the chief agencies for the treatment of epileptic children. Education and training, whether scholastic or manual, should not be prolonged over two and a half or three hours per diem.—Dr. HENRY RAYNER deprecated the regular use of bromides and referred to the greater importance of diet and the regulation of the bowels in the treatment of patients. A few cases of epilepsy tended to improve before puberty or the period of the second dentition.—Dr. J. MILSON RHODES spoke of the insufficient provision for epileptics in this country as compared with the United States and the continent. Schools for epileptics should have plenty of land and playground for the inmates.—Dr. ROBERT JONES spoke in favour of the use of bromides in epilepsy.—Dr. W. LLOYD ANDRIEZEN would not recommend the use of bromide of potassium since potassium was a cardiac depressant. He always used the salts of sodium and ammonium and had found a combination of ammonium bromide (from 10 to 15 grains) and antipyrin (five grains) more effective in removing stupor and dulness and irritable temper of the patients than potassium bromide.

Dr. C. H. BOND read a paper on the Study of the Body-weight in Relation to Mental Disease. He had systematically adopted a plan of weekly weighing of patients suffering from certain forms of insanity at the Horton Asylum and found the curve of weights plotted on the charts a valuable indication having a prognostic value.

The meeting then closed for the day.

At the resumption of the meeting on the following day (July 22nd) Dr. A. W. CAMPBELL gave a lantern demonstration with description of the appearances of various parts of the Cerebral Cortex of Man and Mammals, the histological differences of structure being associated with the localisation of function in the various cerebral areas. The discovery of Flechsig with regard to the presence of "association centres" in the brain was upheld and its important bearing on our future knowledge of neurology and psychology was pointed out.

Dr. JOHN TURNER, assistant medical officer of the Essex County Asylum, read a paper on the Anatomy of the Nervous System, with special reference to the doctrine of continuity of the neurons. Lantern slides were shown illustrating the pericellular networks of fibrils surrounding the large pyramidal cells of the cortex, which were mainly composed of the branching terminals of a class of small nerve cells designated "dark-staining" or "intercalary" cells. This, said Dr. Turner, was an anatomical fact but he could not as yet point out its physiological or psychological significance.

Dr. W. H. B. STODDART read a paper, illustrated with numerous excellent diagrams and stereoscopic slides, on the Psychology of Hallucinations in which an attempt was made to explain the mechanism underlying illusions, hallucinations, and delusions, and to estimate the extent to which the ideational element (as distinguished from the merely peripheral stimulus) entered into the composition of these respective states.

Dr. G. M. ROBERTSON, medical superintendent of Larbert Asylum, Scotland, read a paper dealing with the Treatment of Lunatics in Modern Asylums in contrast with the conditions which prevailed 60 years ago.

Dr. J. CARSWELL read a paper dealing with the Provision for the Care and Treatment of the Occurring Pauper Lunacy of Glasgow and expressed his belief that lunacy was not on the increase in Glasgow.

Dr. RHODES read a paper on the Question of how to provide Accommodation for Chronic and Incurable Cases of Mental Disorder, referring to the provision made on the continent as compared with that in England.

The proceedings then terminated.

THE SOCIAL AND ECONOMIC POSITION OF MEDICAL PRACTICE ON THE CONTINENT.

(Continued from p. 244.)

IN our first article under this heading we dealt with the information supplied from Austria and Germany and we now pass on to consider the situation existing in France. It will be remembered that we sent a series of six queries to trustworthy quarters in the various countries, these queries being designed to elicit opinions relative (1) to the satisfaction or otherwise of the profession with their social status and pecuniary returns, (2) to the existence of a distinction between general practitioners and specialists or consultants; (3) to overcrowding, (4) to contract work, (5) to the legality or otherwise of unqualified practice, and (6) to hospital abuse

FRANCE

1 There is among medical men generally an evident feeling that their position is not what it ought to be and that something is wrong somewhere This is due not to any want of consideration for the medical profession on the part of contemporary society but to the inadequate remuneration obtainable from medical practice The profession enjoys a real influence in French society, medical men have occupied almost every position connected with the government of the country and have been recipients *of honours of all kinds* The jokes of which they are often the object in stage plays and novels are no more than proofs that this influence is in certain quarters regarded enviously From the point of view of material prosperity *things are, however, quite otherwise,* because the general idea to-day is that a medical man is an individual either having private means for pursuing his studies or else making much money, which is unfortunately only true of a dozen Parisian consulting physicians to whom the public constantly point when the *others complain of their lot Under the influence of this* idea the medical profession has been loaded down by the heaviest taxes, one twelfth of the price of rent, doubled in Paris by municipal taxes These taxes fall more heavily on the medical man because his rent is necessarily high in order that he may have a house in accordance with the requirements of his patients rather than with his personal needs, a circumstance which hardly exists in other professions From the social point of view the medical man is burdened with heavier obligations than a member of any other pro*fession The increasing tendency of the democratic ideal is* to give free medical attendance to a larger and larger number in the social category, workmen, employés, and so on; every large organisation causes a crowd of individuals to be cared for at its expense by a single medical man whom it pays at the lowest possible rate, an indifferent post which is always accepted by a beginner and which goes on from beginner to beginner, unless the bait of a decoration at the end of 20 years of this voluntary servitude induces some practitioner to hold the appointment permanently In fact the number of people who pay their medical attendant is gradually decreasing from all these causes while the number of practitioners is increasing Even among patients belonging to the middle and upper middle classes every medical man attends his relatives and his intimate friends gratis *which is a loss not for him but for* the others It is thus easy to calculate that in Paris of 2,714,000 inhabitants one half avoid paying any medical fees at all, 1,000,000 only pay a nominal price, and there remain hardly 200,000 families constituting the real practice of the 3342 existing physicians, each of whom has to attend at least 20 *well-to-do persons* gratuitously *on account of being* relatives or friends, so that " ' [illegible] reduced by about 60,000 The [illegible] of travellers makes, fortunately, [illegible] foreign medical men desirous of competing with the French practitioners in this branch of practice spare no pains in *order that they may be able to take part in it. The general* idea according to which the medical man makes a large income is so widely spread that when there is a question of fees between a practitioner and his patient the courts decide against the medical man who scarcely dares to claim his due where it is refused him

2 There is not a very sharp line drawn between general or family practitioners and hospital physicians The latter, in fact, are ready to become family attendants to wealthy households because their number has grown so great on account of the increase of hospitals that they cannot live as comfortably as they wish while confining themselves to the position of consultants There are even young hospital surgeons who do not hesitate to engage in general practice In reality everyone does what he can to extend his practice and there is only a small number of specialists who are real slaves to their specialty and who refuse to undertake whatever comes to them One barrier exists between the two classes of practitioners, it is a sort of fellow feeling, such that a hospital physician having a patient to send to another practitioner never sends him to any but another hospital physician

3 There is evidently a *superabundance of medical men* The actual proportion is 18,871 medical men for 39,000,000 inhabitants, or one medical man for 2066 inhabitants This enormous number is due to two causes, first, the exemption from two years of military service out of three which benefits medical students, and, secondly, a considerable influx of foreign students, especially Russians and Roumanians Since a year ago there has been an abatement in this, because *foreign students are no longer permitted to* dispense with part of the examination imposed on French students To be more exact, this favour is only granted now to those who wish for the French diploma without meaning to practise in France For those who wish to practise in France the same preliminary examinations are required as for the French students When this regulation came into force the numbers of these foreign candidates immediately decreased

4 Special contracts are made by certain societies or associations with medical men to the effect that all their members shall be attended by the year for a fixed sum The details of the arrangement vary the medical man may either receive a certain *sum for attending* a *number of* individuals whatever visits he may make during the year, or he may receive a fixed sum with the addition of one or two francs for each member, or he may receive a small sum besides for each visit These organisations, of which the friendly societies (*sociétés de secours mutuels*) represent the most formidable type, are one of the principal causes of the weakening of the medical profession, particularly in the provinces When there is only one medical man in a district it is not unusual to find the people forming in this way a veritable combination against him Half of the population is enrolled in a friendly society from which the unfortunate man only draws a reduced tariff, while to the other half which is classed as indigent he gives free medical attendance in exchange for an honorary title In agreements of this kind the medical man's *time is his own, except that which is required for the work* of the society, it is very rare for a practitioner to hold such an appointment on condition that he does not accept other patients

5 There are laws against quackery but they are hardly ever enforced, almost all quacks when they are prosecuted find defenders who set in motion political influences thanks to which the judges abstain from convicting them or only condemn them to ridiculous penalties which are by no means deterrent According to the law, no man may be called doctor unless he is in possession of the diploma of doctor of medicine *However, difficulties have arisen since the recent* creation of the diploma of doctor of pharmacy, the holders of which diploma naturally seek to avail themselves of the confusion In the lower category, that of the so-called health officers, suppressed ten years ago as regards new entries, but of which there still exist more than 1200 representatives, the usurpation of the title of doctor is frequent A singular legal decision has even put them in the right by stating that since they had the right to practise medicine they did not act illegally by taking this title and could only be punished by a trifling fine for causing themselves to be mistaken for the other doctors

6 One sees, unfortunately, only too many people making use of the hospitals who might pay their medical attendants the usual fees Public opinion tends to confound salaried people of every sort with the really poor and to claim for them the same privileges Charity is thus diverted from its true end and becoming a means of economy is nothing but a swindle The abuses have become such that a certificate of poverty or the production of a rate or tax paper proving *that the individual does not pay more than a certain sum* in rates or taxes is now required both for out-patients and in patients But many abuses still exist, particularly in surgical cases, and it is, sad to say, often the medical men themselves who cause them by giving letters of introduction to the surgeon to patients whom they wish to oblige by helping their economies at the expense of their *confrères*

Finally, there are *enormous abuses in the sending to the* hospitals of workmen injured by accidents during work. These workmen by receiving benefits from the rich assurance companies ought not to be regarded as poor persons having a claim to free medical attendance.

Obituary.

SIR JOHN SIMON, K.C.B., F.R.S., D.C.L. OXON., LL.D. CANTAB. & EDIN., M.D. (HON.) DUB., M.D. ET CHIR. (HON.) MUNICH,

FELLOW AND PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; FELLOW AND PAST VICE-PRESIDENT OF THE ROYAL SOCIETY; PAST PRESIDENT OF THE PATHOLOGICAL SOCIETY OF LONDON; FORMERLY MEDICAL OFFICER OF HER MAJESTY'S PRIVY COUNCIL AND CROWN MEMBER OF THE GENERAL MEDICAL COUNCIL; BUCHANAN MEDALLIST OF THE ROYAL SOCIETY.

John Simon, who did more than any other worker of the Victorian era to prevent disease and to prolong life, afforded in his own person an excellent example of the principles which he so strenuously and so fearlessly inculcated. Born in the second decade of the last century, after a career of altogether exceptional brilliancy and usefulness he has passed away in 1904 at the advanced age of 88 years. He had outlived all his fellow workers and there is practically no one left to tell at first hand the story of his life. Even to many of our oldest medical officers of health the name of Sir John Simon is little more than an honoured expression, while in the case of the younger generation of officials and of students of hygiene it is associated in somewhat nebulous fashion with the earliest battles which were waged by sanitary science and administration against preventable mortality and suffering.

Fortunately for history, and as if, indeed, John Simon foresaw that none of his immediate contemporaries would be left to tell in detail of his battles, he has left behind him what will for all time be regarded as a classic contribution to the progress of preventive medicine in this country. Simon's "English Sanitary Institutions" contains not only the story of his own work but also a record of the labours of all those who since the beginning of real sanitary progress in this country have taken a leading part in the fight. As a literary production this volume is of the highest order and the true beauty of its language and the broad humanity of its teaching can be best appreciated by those whose ideals lead them in the direction in which Simon's thoughts and aspirations tended. Simon has died what he himself would have termed a natural death. As, indeed, he tells us in the annual report of the General Board of Health for 1858:—

> *Death by old age* is, physiologically speaking, the only normal death of man. .. . Death virtually by old age comes to some men even before their sixtieth year. To most men it comes much later. A few complete their fifth vicenniad and even carry far into it their noblest mental endowments. ..... And it cannot be far from the truth to assume that, even if there were no artificial interference with the duration of life, death by natural decay would in this country under its present circumstances usually happen at about 80 years of age. Now little more than a tenth par [illegible] happen at 75 years and upwards and *thus,* [illegible] one *may say that at least* nine-tenths of th[illegible] more or less prematurely.

Simon, who was the last of the 14 children of the late Louis Michael Simon, of Blackheath and the Stock Exchange, was of Anglo-French descent. His early education was obtained at a preparatory school at Pentonville and afterwards at Greenwich. Subsequently he was sent into the family of a German pastor at Hohensolms and after a sojourn there of less than a year he was in 1833 apprenticed to Mr. Joseph Henry Green, the first professor of surgery at King's College and surgeon to St. Thomas's Hospital. In 1838 he took the Membership of the Royal College of Surgeons of England, and two years later was appointed assistant surgeon to King's College Hospital. Five years later, and at an exceptionally early age, the blue riband of science was conferred upon him, for he was elected a Fellow of the Royal Society as a result of a paper on the Comparative Anatomy of the Thyroid Gland; and two years later, in 1847, he was appointed lecturer on surgery at St. Thomas's Hospital. Before this date he had contributed articles and papers on scientific, social, and philosophic subjects which bore evidence that he possessed a genius which tended especially in the direction of a remarkable power of concentration and generalisation in connexion with social and scientific subjects.

Before dealing with the work with which Simon's name will always be associated it is necessary that some idea should be conveyed of the sanitary condition of the people at the period when this work commenced. Edwin Chadwick's labours had really begun about ten years before Simon joined the ranks of the medical profession and in 1832 Chadwick had been appointed one of the assistant commissioners to inquire into the working of the Poor-laws. In this capacity his signal abilities were soon manifest and shortly afterwards he became secretary of the newly created Poor-law Commission. It was the work of this commission and of Dr. Neil Arnott, Dr. Southwood Smith, and Dr. J. P. Kay, the medical inspectors connected with it, which first drew the attention of the public and of Parliament to the eminently unwholesome conditions under which the poor of this country lived and laboured, and a synopsis which Chadwick compiled from the elaborate reports of the medical inspectors and which he termed a "General Report on the Sanitary Condition of the Labouring People of Great Britain" led in its turn to the appointment of a Royal Commission to inquire into the allegations there set forth. The Commission issued its final report in 1845 and the recommendations which accompanied that report were, as is now well known, the work of Chadwick himself; indeed, the Commission, in place of treating Chadwick as a reporter whose facts and inferences were the subject of an inquiry, soon appreciated his work and worth and welcomed him as a collaborator and adviser. The report of this Commission was responsible for the passing of the Public Health Act, 1848, and the creation of the General Board of Health, and shortly afterwards there was additional legislation to provide for the care of the metropolis which was exempted from the operations of the Public Health Act of 1848. But the General Board of Health did not yet number among its members a medical man, and it was not until two years afterwards, under the dread of approaching cholera and under the cloak of the Interments Act, that power was given to add a medical man to the *personnel* of the Board, when Dr. Southwood Smith was elected to the office. This ludicrous association of a medical man with the Interments Acts called forth from Dr. Rumsey the following caustic criticism:—

> Who would have thought that in the last decade of advancing civilisation and in a nation boasting of its intellectual and material resources, of its administrative energy and efficiency, the whimsical experiment should have been actually tried of appointing three non-medical authorities—two lords and a barrister—to preserve the health of the living, and then, after a year or so of doubtful success, calling in a physician to bury the dead?

But despite this lay antagonism to the medical profession—an antagonism which is still occasionally to be found in official circles—the public conscience was awakening. Voluntary bodies having for their object the amelioration of the unwholesome condition of the poor were being formed, and in 1850 there was founded the Epidemiological Society of London to study the causes which led to premature death and preventable disease and to advise administrative bodies thereupon. Among the founders of this society were practically all the leading scientific spirits of the day and the last survivor of that little band has just passed away in the person of Sir John Simon. The development of the idea of prevention which was taking place at this time was admirably represented by Lord Palmerston when, in response to an appeal to appoint a great religious fast in consequence of the advent of Asiatic cholera, he wrote: "It did not appear to Lord Palmerston that a national fast would be suitable to the circumstances of the present moment. The Maker of the universe established certain laws of nature for the planet in which we live; and the weal or woe of mankind depends upon the observance or neglect of those laws." But this powerful advocacy notwithstanding, all did not go well with the General Board of Health. The Board was in effect Chadwick and he, with all his intense earnestness, had not the scientific knowledge or the tact to appreciate the case of his opponents. A powerful reaction against what was regarded as his too masterful policy was the result and such reaction soon ended in disaster. According to the provisions of the Act of 1848 the Board was to continue to operate for five years, but in 1854, after a long debate during which much vituperation was levelled against Chadwick, the Government was defeated on a proposal to renew the Act. Subsequently, however, a modified Act was passed which was subject to annual renewal and which constituted a new Board of Health, consisting in point of fact of a president who was provided with certain expert advisers. Sir John Simon in his "Institutions" discusses with eminent fairness and sympathy the circumstances which in effect brought the

SIR JOHN SIMON, K.C.B., F.R.S.

first Board of Health to its end, summing up in these words:—

> [illegible] ing is a not ignoble excuse for such signs of over-eagerness as he may have shown.

By this unfortunate termination of the first General Board of Health the services of both Mr. Chadwick and Dr. Southwood Smith, the first medical member of the Board, came to an end. At this juncture Simon became the principal actor on the scene. Simon owed his first appointment in the sphere of prevention to the fact that even at that remote period local authorities were able by means of Acts of Parliament to provide themselves with special powers, and in accordance with the recommendation of the Health of Towns Commission, a few cities were beginning to appoint medical officers of health. To the town council of the city of Liverpool belongs the honour of having in 1847 appointed the first official of this class, and in 1848 the Corporation of London was fortunate enough to secure Simon's services in a like capacity.

Although his City appointment had attached to it a few loosely defined statutory duties the conception of a medical officer of health was entirely new and the office was practically what its first holder chose to make it. Simon went to work on lines which are now familiar enough but which in those days were entirely novel. Almost the first step was to obtain information as to mortality. By a [illegible] the 11 Poor-law medical officers of the City. With the aid of these returns a routine of weekly inspections was instituted, at first restricted to particular premises where certain sorts of disease or death had occurred but afterwards developed to a methodical sanitary superintendence of all the poorer parts of the City, at that time including some 7000 inhabited houses. The overcrowding which then existed among the poor population of the City and elsewhere in London was habitually of the grossest description. Many courts, alleys, and individual dwellings teeming with inhabitants were totally unfit for habitation; light and ventilation were still hindered by the window-tax; there existed no provision whatever against the spread of infectious diseases, typhus fever was common, and the death-rate, judged by modern town standards, was appallingly high. Water was delivered unfiltered. Much of it was either fetched from standpipes or stored within the dwelling in cisterns and receptacles of the most objectionable kind. The sewage of London was discharged directly into the Thames. There were some 130 slaughter-houses within the City boundaries, nearly half of which were underground vaults and cellars. Burials still took place in City graveyards and, among the poor, bodies of persons who had died from infectious disease were habitually kept in the room a week or more before burial. The adulterations of food, which about that time were being exposed by THE LANCET Analytical Commission, were common there as elsewhere in London and were altogether uncontrolled, while no sort of check was exercised over unwholesome or dangerous conditions of labour which abounded. The medical knowledge of the time could throw very little light upon the manner in which many of these objectionable conditions operated to produce unhealthiness and death, but Simon had no lack of evidence of the fact that they did so. During his tenure of office much was done by the City authorities on his advice in the direction of improvements in sewerage and [illegible] ent of periodical house [illegible] tice of scavenging, and by [illegible] ances." In particular the [illegible], and Simon congratulated the Corporation that in 1855, at a time "when cess-pools were still almost universal in the metropolis, and while in the mansions of the West-end they were regarded as equally sacred with the wine cellars, they had been abolished, for rich and poor, throughout all the square mile of the City."

The effect of Simon's work as medical officer of health was far more than local. His annual reports, which cover the years 1848 to 1855, form a landmark in the history of English sanitation. They gave the result of systematic surveys of the general sanitary circumstances of the City and of the risks arising from cholera and other diseases, they ventilated questions of housing and other social conditions of the labouring classes, and they poured a flood of light upon a great variety of other matters affecting health. They showed the causes of the evils described and the ways in which they could be remedied. The subjects thus dealt with were then unfamiliar. For many it was a new way of looking at social questions. The sufferings and the degradation which were incurred through the conditions of life of a large section of the labouring classes were not realised and it needed writings like Simon's to show how vain it must be to expect good social fruit from human life which has to run its course under such conditions. These reports, written in the masterly terse English for which Simon was always famous, took hold of the public imagination and were in demand in many quarters. They were subsequently republished with a valuable preface, written in anticipation of a future reorganisation of the General Board of Health, entitled "A Ministry of Public Health." In this essay Simon foreshadowed the ideal to which later he was to give his best energies in striving to attain, viz., a department of Government, with a constituted Parliamentary head, having the duty, "in the widest sense, of caring for the physical necessities of human life." Many of the passages in this essay are striking and we are tempted to quote the following as illustrating Simon's wide conception of the relation of Government to medical affairs:—

> The legislature recognises no medical authority. Occasionally this fact stands out in painful conspicuousness and brings most injurious [illegible] —before Par- [illegible] legal proceed- [illegible]

In 1853 Simon was appointed one of the commissioners to inquire into the tremendous outbreak of cholera at Newcastle and Gateshead. In 1854 the General Board of Health obtained power to appoint a medical officer and Simon was offered and accepted the appointment, which four years later, on the dissolution of the General Board of Health in circumstances to which we have already alluded, became that of medical officer to the Privy Council. During these four years little could be done towards inaugurating a public health policy for the country. The Board of Health, established in 1848 at Chadwick's instance and working on Chadwick's lines and without medical advice, had been too precipitate. When Simon was appointed the work of that Board had lately been fiercely criticised in Parliament and supported only half-heartedly by the Government. The post of medical officer for a time was merely renewed from year to year after Parliamentary discussion; it was made permanent in 1858 when the functions of the Board were transferred to the Privy Council and then only by a narrow majority of six votes after a debate in which Simon's services and work were warmly defended by Mr. Lowe (the late Lord Sherbrooke). During this period of uncertainty Simon had already shown what valuable work could be done by a central medical department. In 1856 he submitted a report reviewing all the inquiries which had been made for the Board of Health into the London cholera outbreaks of 1848-49 and 1853-54, demonstrating conclusively the relation of these epidemics to polluted water-supply and setting out the well-known contrast in cholera incidence afforded in 1854 between the areas supplied by the Southwark and Vauxhall Company and those supplied by the Lambeth Company which originally had been brought out by Dr. Snow's researches. In 1857 he issued the well-known "Papers on the History and Practice of Vaccination," a quarto volume summarising the knowledge and opinions with regard to vaccination at that time, together with a report in which Simon addressed himself to the following questions: (a) What kind of evil was small-pox before vaccination arose to resist it? (b) What facts and arguments led to the first sanction of vaccination and to what sort of inquiry were they subjected? (c) What further knowledge, at the end of half a century's experience, has been gathered as to the protective powers of vaccination? (*d*) What evils have been shown to attend its practice or to counterbalance its alleged advantages? (*e*) How far are there realised in this country those benefits which can reasonably be expected from the general [illegible] ? In 1858 followed the "Report on [illegible] of the People of England," an essay in [illegible] r. Greenhow's work on the prevalence of diseases in different districts of England and Wales, which, for the first time, demonstrated many of the wide variations which exist in the local incidence of certain diseases, and strongly emphasised the need for impartial skilled inquiry and publication of facts in all such cases. All this made the arguments for the establishment of a medical department of the Government overwhelmingly strong and in 1859, after the functions of the General Board of Health had become absorbed by the Privy Council, John Simon was permanently appointed medical officer to the Privy Council.

The jurisdiction of the Privy Council in sanitary matters was limited. The Council had certain statutory duties with regard to public vaccination, epidemic regulations, quarantine and the Medical Acts, as well as a general power of inquiry into "any matters concerning the public health in any place or places." Here, as in his City appointment, the degree of importance and usefulness of medical officership depended on what the medical officer made it. Simon, needless to say, saw his opportunities and used them to the full. He got together a brilliant staff of workers—it is sufficient to mention the names of Seaton, Ballard, Burdon Sanderson, Bristowe, Buchanan, Thorne Thorne, and Power, all of whom at one time or another worked under his direction—and organised a thoroughly efficient inspectorate. The position of public vaccinator was then very unsatisfactory; the system, as administered by the Poor-law Board, without medical advice, had failed to secure efficiency or even method, and a large part of the work of the new department was devoted to obtaining information on which reforms had to be based and which led ultimately to the Vaccination Act of 1867. Vaccination supervision, indeed, throughout formed a large part of the work of the department, partly because Simon was strongly impressed with the necessity of inspection to secure the efficient performance of public vaccination, and partly also because he saw the advantages of utilising and developing in various directions a system which carried his inspectors to all parts of the country. Comprehensive inquiries were also undertaken into the incidence of particular diseases on localities and the circumstances of their spread. These inquiries, together with Simon's summaries of their results, appear in the well-known series of Privy Council reports from 1859 to 1872. They included many classical investigations—for example, those into diphtheria, the diseases of the cotton famine, cerebro-spinal meningitis, and cholera. Systematic investigations were also undertaken into habitually prevalent diseases—epidemic diarrhœa, pulmonary diseases, phthisis, causes of infant mortality, and the like. In 1862-63 an important inquiry was undertaken into establishments where dangerous industries (in connexion with lead, mercury, phosphorus, and arsenic poisoning) were carried on. In 1863 also a survey was made of the hospitals of the United Kingdom, having for its object inquiry into the accommodation afforded by each of them for the treatment of different diseases and into their respective sanitary conditions. In the same year inquiries were made with regard to accidental and criminal poisoning, and in 1864-65 was issued the result of a laborious inquiry into the dwellings of the poorer labouring classes in town and country. Other work undertaken was the adaptation of the then existing system of registrar-general's returns and statistics to sanitary requirements, with the result of initiating the present valuable series of decennial supplements issued by the General Register Office. A few other important matters may be mentioned in this necessarily brief summary of the best period of Simon's enormous labours: the organisation which he established to deal with cholera in the epidemics of 1865-66 and with small-pox during the great epidemic of 1871; the initiation in 1870 of a scheme for laboratory work in connexion with public health matters; and the dealings of the department with questions of quarantine. In his uncompromising opposition to the objectionable and useless practice of quarantine Simon did a great service to this country; he laid down principles of dealing with imported infectious disease which still govern our practice and which now are slowly being accepted by foreign nations. The present system of port sanitary authorities and port inspection had its origin in the organisation which Simon began to promote in 1871.

During the period of Simon's tenure of office under the Privy Council he was largely instrumental in obtaining the enactment of the Sanitary Act of 1866, the Pharmacy Act of 1868, and other legislative measures. With increase of sanitary legislation, actual and prospective, it became evident that the establishment of local sanitary authorities on a wider scale, together with the e [illegible] of central control and direction over [illegible] uthorities, had become necessary to [illegible] e chaos of local government at that time is well known and no one has described its difficulties and drawbacks so well as Simon. The Government in 1868 appointed a Royal Commission to inquire into the operation of various sanitary laws and their administration, including the constitution of the administrative authorities, central and local, and the formation of local sanitary areas. The report of the Commission in 1871 was to the effect that "the administration of the laws relating to public health and the relief of the poor should be presided over by one Minister ...... an arrangement which would probably render necessary the appointment under him of permanent secretaries to represent both departments." Simon viewed this report with some misgiving. The proposal to unite his department with the Poor-law Board might or might not be advantageous for sanitary progress; all would depend upon the Minister who controlled and arranged the early organisation of the new department. But the Commission had excluded from its reference much of the best work which the medical department of the Privy Council had been doing—work which was essentially national and had little or no concern with local government. There were, for example, all the questions relating to industrial diseases and the regulation of unwholesome conditions of employment, and numerous matters concerning the administration of the Medical and Pharmacy Acts. In Simon's view it was essential that these and other large questions of medical policy should be dealt with by a department which would fulfil the proper duties of a Ministry of Health, and it was a serious objection to the proposed Local Government Board that it afforded so little promise of developing into an efficient health department of the Government. The Local Government Act of 1871, creating the Local Government Board, gave him little encouragement. The recommendations of the Commission were further narrowed in the Act. Even then, if a satisfactory policy had been inaugurated when the new department began its labours the initial blunders might have been rectified. But Simon's worst fears were realised. The new Local Government Board, under the direction of its first president, Mr. Stansfeld, lost a great opportunity. It became practically the old Poor-law Board under a new name, continuing all the unsatisfactory traditions of petty interference and over-centralisation which characterised that bureau, while the medical department was placed in a position wholly subordinate to the Poor-law secretariate. Simon had then to witness the mischief done by the Poor-law staff in dealing, without his advice, with the formation of districts for medical officers of health, with the system of grants and repayments to sanitary officers, with appointments of joint districts—a colossal series of blunders from which the public and the whole sanitary service are still suffering. Medical investigations were cut down and restricted in all kinds of ways, and the work which Simon could have effected so ably by means of his staff was handed over to Poor-law inspectors, without knowledge either of public health or of sanitary administration. The position became more and more untenable and to Simon, with his great record of hitherto continuous progress, it became intolerably bitter. The policy to which Mr. Stansfeld had lent himself had become practically fixed in 1874 and when a change of Ministry occurred in that year little improvement was to be looked for. Simon retired disheartened in 1876. Writing in later years in "English Sanitary Institutions" he gives a vivid picture of the opportunities of the time and of the way in which they were lost. "Though many years have intervened I do not refrain from saying how grievously wrong I believe to have been the policy of the system represented. In relation to the flag under which I had had the honour of serving I regard it as having been virtually a policy of retreat."

It is probable that the Local Government Board is now in many ways less open to reproach for neglect of the medical side of its work than in the days when Simon left its service. It is at any rate certain that the medical officer of the Board and his staff now have duties and responsibilities which are far wider and more numerous than they were 28 years ago. But it is notorious that the brilliant scientific and administrative work which has been done by Simon's successors has been achieved in face of a host of inter-departmental difficulties created by the objectionable system against which Simon protested and which it is to be feared still largely prevails. Considering subsequent events in the light of Simon's essays and protests it is impossible not to realise how much higher would be the present position of the whole sanitary service, and how much greater and more general would have been the improvements effected in the whole sanitary condition of the country, if Simon's wider and statesmanlike conception of a Ministry of Health had been adopted. We believe that the formation of such a ministry is not only still desirable but that from many circumstances it is still more imperatively called for than it was in Simon's day. We may quote the following passage from his earlier writings regarding the formation of a Ministry of Public Health:—

> [illegible] there in that beastly [illegible] king such water. [illegible] s thought of the bone- [illegible]; what of the sewer grating before the door; what of the Irish basket-makers upstairs—12 in a room—who came in after the hopper and got fever; what of the artisan's dead body stretched on the widow's one bed beside her living [illegible] cept against wilful [illegible] be law. Fragments [illegible] ugh to establish pro- [illegible] sion of a principle, [illegible]

So far as these lurid conditions do not any longer exist the fact is a testimony to the work of Simon and his coadjutors, but the very circumstance that so much has been done with faulty organisation should encourage the Government to have more confidence in its trained sanitarians and to face boldly the question of a properly organised and subsidised Public Health Department.

Such was the versatility of Sir John Simon, at so many points did he touch the intellectual life of his time, that it would be misleading if we considered him merely from the sides of scientific or of official achievement. Simon was, indeed, much more than a great officer of health and writer on preventive medicine, hygiene, and surgery. He belonged to the highest type of the man of culture and progress in the middle of the last century. When we think of Buckle, of George Henry Lewes, of Claude Bernard, of Charles Kingsley, and of Ernest Renan, we must perforce think also of Simon who was their friend. He was a social force in quarters where science seldom shows her face—among distinguished circles, both literary and artistic, political and social, where the man of science is only too apt to be regarded merely as the enemy of æsthetics or the chiller of enthusiasms. John Ruskin was Simon's intimate friend and Simon appeared as an executor in his first will. Simon was also intimate with the whole pre-Raphaelite circle and it was united in its affection for the little officer of health, so small in stature but great in intellectual dignity, in lofty intelligence, and moral worth.

In his old-fashioned house in Kensington-square gatherings used to take place for many years, from 1867 onwards, of men who had the real right to be considered celebrities. Leaving on one side the brilliant men of science and the pioneers of Simon's own especial work, many most distinguished French, German, and American thinkers and writers, we may mention Thackeray, Kingsley, Tennyson, Rossetti, Burne-Jones, Jowett, Woolner, who all and often assembled in what they felt to be a congenial atmosphere of liberality and learning. And Simon loved to be surrounded by such friends. He was devoted to the grand style in art and in letters and in later years, as he sat patiently on his sofa battling hour by hour with the pains of venerable age, he would brighten up in an extraordinary way at some chance mention of a favourite author, some painter he had once known, some thinker he had once argued with. A partial loss of eyesight had plunged him, as he said, "in a great darkness" and he must have had many long meditative vigils, but he ended his days among troops of truly devoted relatives and friends, the circle of the latter having been ever recruited. Those who enjoyed the privilege of being included in his list will always think with deep affection and reverence of the great sanitarian who dressed and shaved after a bygone fashion, sat in the familiar room, and awaited the end among the ghosts of the great men of a great century, himself a pathetic and noble shadow soon to join them. That end came last Saturday, July 23rd, after a short period of unconsciousness.

A collected series of Simon's reports, edited by Dr. E. C. Seaton and published in 1887 by the Sanitary Institute, should be read by all sanitarians. "English Sanitary Institutions" was first published in 1890, and a later edition, with various additions, in 1897. Soon after his retirement, in 1878, Simon was elected Preside[illegible] geons of England. He had [illegible] Council (1868–1880) and Vi[illegible] of office under the Privy Council he had taken a deep interest in all questions relating to the organisation and status of the medical profession and had been concerned officially in securing the Medical Act of 1858 and in promoting the Medical Acts Amendment Bill which fell through in 1870. Some of his well-known essays on the position of the medical profession were reprinted in the public health reports above referred to. After his retirement Simon accepted a nomination as Crown member of the General Medical Council, on which he continued to serve till 1895. At the time of his death Simon had been longer on the roll of the Royal Society than any other Fellow. He was a Vice-President of that society from 1879 to 1880. He received numerous honorary degrees from universities at home and abroad. The recognition which he received from the Government on his retirement was merely the decoration of C.B.; he was made K.C.B. on the occasion of the Jubilee of 1887.

CHARLES KELLY, M.D., F.R.C.P. LOND.

Dr. Charles Kelly, medical officer of health of a large portion of Western Sussex, died after a very short illness on June 16th at his residence in Gratwicke-road, Worthing. The deceased, who was 59 years of age, appeared to be in his usual health on June 14th and attended a meeting of the sanitary, baths, and burial committee of the town council held at the municipal offices, Worthing. On June 15th, however, he was seized with illness which terminated fatally on the evening of the following day. Dr. Kelly's medical education was received at King's College, London. In 1866 he graduated as M.B. at the University of London, obtaining a university scholarship in medicine and midwifery; in the following year, when he took the degree of M.D., he had the distinction of being gold medallist. In 1866 he was also admitted M.R.C.S. Eng. and in 1880 he was elected a Fellow of the Royal College of Physicians of London. At King's College Hospital he held the appointments of house physician and resident accoucheur; he was also a Fellow of King's College where for some time he was professor of hygiene and curator of the museum. In March, 1874, he was appointed medical officer of health of the combined district of West Sussex, including the urban authorities of Arundel, Horsham, Littlehampton, Portslade, Southwick, and Worthing and the rural district authorities of East Preston, Horsham, Midhurst, Petworth, Steyning (East and West), Thakeham, and Westborne. The area of the district is, of course, very extensive and the population, which at the time of Dr. Kelly's appointment in 1874 was about 96,000, had risen in the census year of 1901 to 122,604. For a few years he resided in Horsham, but eventually he removed to Worthing. Dr. Kelly was a man of many attainments and possessed considerable literary ability. He was the author of a number of reports on the general health conditions of his district as well as on outbreaks of enteric fever in Worthing; one of these, which occurred in 1893, was the subject of a great many references in our columns. He was a Fellow of the Royal Meteorological Society and the Worthing meteorological records were compiled under his supervision. The funeral took place at Broadwater Cemetery on June 20th.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8565 births and 4142 deaths were registered during the week ending July 23rd. The annual rate of mortality in these towns, which had been 13·5, 13·5, and 13·7 per 1000 in the three preceding weeks, further rose last week to 14·1 per 1000. In London the death-rate was 14·8 per 1000, while it averaged 13·9 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 3·1 in West Bromwich, 5·5 in King's Norton, 7·1 in Willesden and in Leyton, 7·4 in Northampton, 8·3 in Hornsey, and 8·6 in Hastings; while the highest rates were 18·2 in Birkenhead, 18·6 in Bootle, 19·3 in Sunderland, 19·6 in Rhondda, 19·7 in Burnley, 20·0 in St. Helens, and 20·3 in Liverpool. The 4142 deaths in these towns last week included 792 which were referred to the principal infectious diseases, against 456, 500, and 506 in the three preceding weeks; of these 792 deaths, 428 resulted from diarrhœa, 177 from measles, 91 from whooping-cough, 50 from diphtheria, 24 from scarlet fever, 17 from "fever" (principally enteric), and five from small-pox. No death from any of these diseases was registered last week in Hornsey, Hastings, Ipswich, West Bromwich, King's Norton, or West Hartlepool; while the highest death-rates from the principal infectious diseases were recorded in Aston Manor, Stockport, Wallasey, Liverpool, Bootle, Wigan, Huddersfield, Leeds, and Rhondda. The greatest proportional mortality from measles occurred in Birkenhead, Bootle, St. Helens, Huddersfield, Bradford, Leeds, and Rhondda; from scarlet fever in Hanley and Warrington; from whooping-cough in Burton-on-Trent and Blackburn; and from diarrhœa in Tottenham, West Ham, Birmingham, Aston Manor, Stockport, Wallasey, Liverpool, and Rhondda. The mortality from diphtheria and that from "fever" showed no marked excess in any of the large towns. Of the five fatal cases of small-pox registered in these towns last week, two belonged to Newcastle-upon-Tyne and one each to London, Rochdale, and Gateshead. The number of small-pox patients in the Metropolitan Asylums Hospitals at the end of last week was 51, against 74, 71, and 62 at the end of the three preceding weeks; six new cases were admitted during the week, against ten, ten, and seven in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 1631, 1685, and 1698 on the three preceding Saturdays, had further risen to 1754 on Saturday last, July 23rd; 234 new cases were admitted during the week, against 254, 269, and 229 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 146, 135, and 155 in the three preceding weeks, declined again last week to 120, and were 13 below the number in the corresponding period of last year. The causes of 39, or 0·9 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Salford, Leeds, and in 46 other smaller towns; while the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Warrington, Manchester, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 16·3, 15·8, and 14·8 per 1000 in the three preceding weeks, rose again to 15·7 per 1000 during the week ending July 23rd, and was 1·6 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 11·0 in Leith and 12·3 in Perth to 18·7 in Greenock and 21·1 in Paisley. The 518 deaths in these towns included 23 which were referred to diarrhœa, 22 to whooping-cough, 12 to measles, three to scarlet fever, three to diphtheria, three to "fever," and two to small-pox. In all, 68 deaths resulted from these principal infectious diseases last week, against 75, 64, and 53 in the three preceding weeks. These 68 deaths were equal to an annual rate of 2·1 per 1000, which was 0·6 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 18, 20, and 19 in the three preceding weeks, rose again last week to 23, of which ten occurred in Glasgow, four in Edinburgh, four in Dundee, and three in Aberdeen. The deaths from whooping-cough, which had been 31, 24, and 21 in the three preceding weeks, rose again to 22 last week and included 13 in Glasgow, three in Paisley, two in Edinburgh, two in Dundee, and two in Aberdeen. The fatal cases of measles, which had been six in each of the two preceding weeks, increased last week to 12, of which six were registered in Edinburgh, three in Greenock, and two in Glasgow. The deaths from scarlet fever, which had been two in each of the two preceding weeks, increased last week to three, and all occurred in Glasgow. The fatal cases of "fever," which had been three, seven, and three in the three preceding weeks, were again three last week, and were all recorded in Glasgow, where the two deaths from small-pox also were registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 80, 88, and 49 in the three preceding weeks, rose again last week to 75, but were slightly below the number in the corresponding period of last year. The causes of 26, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 16·5, 17·9, and 19·3 per 1000 in the three preceding weeks, declined again to 17·5 per 1000 during the week ending July 23rd. During the past four weeks the death-rate has averaged 17·8 per 1000, the rates during the same period being 13·4 in London and 15·4 in Edinburgh. The 127 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 13 from the number in the preceding week and included 15 which were referred to the principal infectious diseases, against seven, ten, and 18 in the three preceding weeks; of these, five resulted from measles, five from diarrhœa, three from whooping-cough, and two from "fever," but not any from small-pox, from scarlet fever, or from diphtheria. These 15 deaths were equal to an annual rate of 2·1 per 1000, the death-rates last week from the principal infectious diseases being 2·9 in London and 2·0 in Edinburgh. The fatal cases of measles, which had been two, two, and ten in the three preceding weeks, declined again last week to five. The deaths from diarrhœa, which had been one, five, and two in the three preceding weeks, rose again to five last week. The fatal cases of whooping-cough, which had been three in each of the two preceding weeks, were again three last week. The two deaths from "fever" corresponded with the number in the preceding week. The 127 deaths in Dublin last week included 24 among children under one year of age and 30 among persons aged 60 years and upwards; the deaths of infants showed a very considerable decline, while those of elderly persons were but slightly fewer than the number in the preceding week. Five inquest cases and three deaths from violence were registered; and 52, or more than two-fifths, of the deaths occurred in public institutions. The causes of seven, or nearly 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: W. H. Daw to the *Wildfire*; T. H. Vickers to the *Wildfire* for the *Immortalité*; and H. C. Ross to the *Wye*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel F. B. Maclean proceeds to the Royal Herbert Hospital for duty. Lieutenant N. E. Dunkerton proceeds to London shortly to undergo a course of instruction.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Hudson to be Surgeon-Major (dated July 16th, 1904); Surgeon-Lieutenant H. Stallard, 4th Volunteer Battalion the Sherwood Foresters (Nottinghamshire and Derbyshire Regiment), to be Surgeon-Lieutenant (dated July 27th, 1904).

IMPERIAL YEOMANRY.

Lancashire Hussars: John Tawse Nisbet to be extra-

Surgeon-Lieutenant under paragraph 30 Yeomanry Regulations (dated July 23rd, 1904).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Cornwall (Duke of Cornwall's): Surgeon-Captain J. Ratcliff-Gaylard resigns his commission and is appointed Captain (dated July 23rd, 1904).

[illegible]alion the Queen's (Royal West [illegible] Captain A. M. Hickley resigns [illegible] July 23rd, 1904). 1st Cadet Battalion the Royal Fusiliers (City of London Regiment): Surgeon-Lieutenant A. R. Owst to be Surgeon-Captain (dated July 23rd, 1904).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Woolwich Companies: Maurice Waugh Renton to be Lieutenant (dated July 23rd, 1904).

THE WAR IN THE FAR EAST.

Public interest is, and for the past week has been, focussed on questions and complications connected with the action of Russia in the seizure of British vessels, and it is needless to say that the House of Commons listened with very grave attention to Mr. Balfour's statement thereon on July 25th when, despite the reassuring measures and action promised by the Russian Government, the situation was, and still remains, we regret to say, one of great gravity. As regards the progress of the war it seems to be clear that there has been a great deal of severe fighting with results that have been highly favourable to the Japanese. General Kuropatkin's forces have given way and been slowly driven to the northward, while material gains have been secured by their opponents. As we suggested last week would be the case, there seems to have been a big fight near Tashichiao, which has been captured and occupied by the Japanese, and the Russians have definitely evacuated Newchwang, setting fire to the railway station and destroying their stores before leaving. But the reports from the seat of war are somewhat conflicting and very meagre owing probably to the belligerent generals of both sides being too much occupied in field operations to frame and to forward military despatches. The Russians have been, and still must be, encountering a growing difficulty in the transport of ammunition and food-supplies along the Siberian railway and in working at the same time their system of troop-trains for reinforcing their army in the field. The condition of the R[illegible] which seems imminent has, however, still to take place. The envelopment with which that army is menaced must by this time be nearly, if not quite, complete. As regards Port Arthur, there is much in the nature of prophecy but little or nothing to record in the way of trustworthy news. The Japanese navy has throughout laboured under one difficulty: it has not been of sufficient strength—that is, it has not had a sufficient number of ships to maintain an effective blockade of both Port Arthur and Vladivostock and to secure at the same time the safety of their marine transport system from attack. It is, nevertheless, wonderful what their naval service has been able to accomplish in this war. With regard to the medical and sanitary aspects of the campaign, with which we are, of course, more especially concerned, there is a singular dearth of news. The recent losses on both sides have been severe and the transport by rail of over 300 Russian wounded, of which mention has been lately made, must be but a fractional part of the sick and wounded in General Kuropatkin's war hospitals; indeed, considerations about provision for them may have seriously embarrassed his tactics and freedom of movement. From about the middle of July to the middle of September the roads are, owing to the rains, impassable for wheeled vehicles and movement is confined to the passage of light carts and pack animals so that the sick transport must be a great difficulty to both sides. Completely isolated as Port Arthur is on the land side there must by this time be a large accumulation of sick and wounded in the hospitals of that fortress.

The *Novosti* relates that at a recent meeting of the Caucasian Medical Society Adjutant-General A. N. Kuropatkin, commander of the forces in Manchuria, was elected an honorary member for his constant exertions as to sanitation on behalf of the department under his care and his constantly sympathetic attitude to the medical men under his orders and his efforts to improve their position both as to the execution of their duties and their incomes.

Correspondence.

"Audi alteram partem."

THE INSURANCE OF MEDICAL MEN AGAINST THE DANGERS OF THEIR PROFESSION.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of June 25th, p. 1811, you give a reasonably full account of the case of Eyre *v.* Scottish Accident, Life, and Fidelity Insurance Company, but with such an editorial bias as to obscure the true facts, and as the one mainly responsible for the defence I should like, by your courtesy, to address a word to the profession. An insurance company is a business concern and not a charity and has to be conducted on business lines, and this particular case was not contested for £ *s. d.* but on principle. You make it clear more than once in the course of your article that the company's agent had misled Dr. J. Eyre. Now the first question that was asked at the arbitration was whether the agent had misrepresented things to Dr. Eyre. Both Dr. Eyre's counsel and himself distinctly said "No." Is it fair and honest that this question should be again raised? Yet I find the same false statement in Dr. J. H. Bryant's letter of July 9th. Before opposing this claim I took the opinion of several of the most eminent members of the profession in London who thought Dr. Eyre's contention ridiculous, as the result proved.

With the exception of Dr. Eyre's first letter stating he had contracted Malta fever without any mention of accident (and he failed to find a satisfactory accident after the most careful cogitation) your report of June 25th is complete enough for any medical man to judge of the merits of the case. The case in a nutshell is this: Dr. Eyre contracted Malta fever (a specific fever) and he was insured against certain diseases, but Malta fever was not one of them and he claimed under the heading "septicæmia." On a parity of reasoning typhoid fever, pneumonia, and most other diseases are "septicæmia." I put it to the profession was the arbitrator's finding not right? I am very sorry for Dr. Eyre, whether his claim was founded on carelessness or conceit the result was sad for him. I am sorry for the eminent men who gave all too sympathetic evidence on his behalf, and also sorry for our profession because it only gives our legal friends another opportunity of regarding expert medical evidence in the superlative degree. I am, Sirs, yours faithfully,

JOHN MACGREGOR.

Duke-street, W., July 26th, 1904.

NOTES ON THE PHYSIOLOGICAL ACTION OF "CARBONATED" BRINE BATHS.

To the Editors of THE LANCET.

SIRS,—Since the publication of Professor T. Schott's paper in 1891 so much has been claimed for the Nauheim treatment of heart disease that it has aroused in many minds the natural suspicion which is the fate sooner or later of all reputed panaceas.

Without attempting to discuss any of the controversial points which have arisen in connexion with the treatment, the following notes of experiments made with the brine at the Saltburn baths may be of interest. The analysis of this brine is as follows:—

Sodium chloride	25·365	per cent.
Sodium sulphate	0·066	"
Calcium sulphate	0·402	"
Magnesium sulphate	0·048	"
Calcium carbonate	0·029	"
Water	74·090	"

This percentage of sodium chloride works out at 2400 grains to the pint, very little below the Droitwich water which contains 2700 grains to the pint. The stronger waters, however, do not concern the present paper, all the notes referring to experiments made with water approximating in strength to the Grosser Sprudel at Nauheim. This averages 190 grains to the pint, or rather less than 2 per cent., and no baths have been used here in connexion with these experiments containing more than 5 per cent. of salt.

Brine baths generally may be divided into three classes:

namely, (1) weak, (2) strong, and (3) very strong, containing respectively from 2 to 5 per cent., from 5 to 12 per cent., and from 12 to 25 per cent. of salt. In a future paper I hope to publish the results of experiments now being made with Classes 2 and 3, plain and carbonated, but as I have mentioned already only Class 1 concerns us now. The technique which has been adopted follows the lines laid down by Dr. L. C. T. Thorne,[1] though the first bath is given at a temperature of 96° F., patients objecting to the lower temperatures at first. Later the baths are given at 90° and even 88° but not as a rule below this point.

The carbonic acid gas is obtained from Dr. Sandow's "patent carbonated baths," the number of packets dissolved in each bath being gradually increased. Four ounces of calcium chloride are dissolved in the first bath and this amount is increased by one ounce in each successive bath until the limit of 12 ounces is reached. Baths are given on three successive days, the patient resting on the fourth day.

The question whether the chemical constituents of the baths are capable of absorption by the intact skin has been the object of study for many years and has been answered in the negative by the majority of observers. On the other hand, many continental observers—notably Professor H. Keller[2]—have shown that the skin through imbibition can and does take up certain constituents of the baths; these penetrate as far as the corium[3] and are then taken up by the lymph and blood through osmosis. The quantity thus absorbed must be in any case excessively small and the explanation of the physiological changes that occur must be looked for in the reflex action of a stronger lymph and blood stream.

The physiological changes recognised as following the brine treatment are given by Professor Keller[4] thus: 1. The sense of touch and the sensibility of the skin are both increased. 2. The osmotic pressure is raised. 3. The red blood corpuscles are slightly increased in number whilst the white are lessened. 4. Respiration is slowed and deepened. 5. The intake of oxygen and the output of carbonic acid are increased. 6. The pulse is slowed and the blood pressure is raised. 7. The baths have a distinct influence on metabolic change according to their concentration and chemical constitution, but here all observers are not agreed; in Class 1 (containing from 2 to 5 per cent. of salt) we find: (*a*) increase of urine; and (*b*) increase of chlorides, urea, and uric acid.

I find that in the few cases which I have had the opportunity of studying, these results, which refer only to plain brine baths, are rendered more striking by the addition of carbonic acid gas to the water. The effects are of course most obvious in the circulatory and respiratory systems. Diminution of the cardiac dulness occurs to a considerable extent, but the claim that this change is due to an actual shrinkage of the volume of the organ is difficult to understand; probably the alternative explanation of an increased pulmonary expansion, and the consequent interposition of resonant lung between the heart and the chest wall, is the correct one. The pulse frequency is lessened and the blood pressure is as a rule raised, although occasionally a lowering of the pressure is noticed. According to Dr. Franze,[6] low blood pressures are raised and high ones are lowered but I have not been able to confirm this statement. The heart's action becomes slower, stronger, and more regular and in some cases œdema and cyanosis disappear in a most remarkable manner.

To the patient the subjective effects are often most grateful—sleep is better, the appetite increases, and there is a sense of improved well-being and heightened tone generally.

The greatest care should be taken in the selection of cases suitable for the treatment. In the paper[6] referred to above it is claimed that valvular lesions, simple muscular weakness due to influenza, enteric fever and acute rheumatism, fatty heart, arterio-sclerosis, and angina pectoris may all be benefited by a graduated course of baths.

I believe that what may perhaps be called the indiscreet administration of different baths in the hope that one form or other will hit the mark has a tendency to bring the whole science of [illegible] ..t least certain to cause fr[illegible] worse.

These baths are undoubtedly a most powerful remedial agent and the selection of suitable cases, the consideration of individual idiosyncrasy, and more especially the careful graduation of the treatment are of the highest importance.

As Professor Keller says, clinical experience and careful experimental study must go hand in hand in the elucidation of the physiological and therapeutical effects of the baths; empirical balneology must be done away with before the science can take its place by the side of pharmacology.

I am, Sirs, yours faithfully,
R. ALLAN-BENNETT, M.B. Lond.

Saltburn-by-the-Sea, July 21st, 1904.

THE TREATMENT OF HÆMORRHOIDS AND ALLIED CONDITIONS BY OSCILLATORY CURRENTS OF HIGH TENSION.

To the Editors of THE LANCET.

SIRS,—I crave your courtesy for the insertion of a brief reply to the criticisms on my paper made by Mr. P. L. *Mummery in THE LANCET of July 16th, p. 175. As I shall* shortly be presenting a further communication on the same subject I will now confine myself strictly to the points raised in Mr. Mummery's letter.

1. I am, of course, perfectly well aware that in many cases hæmorrhoids of minor degree can be cured by slight stretching of the sphincter muscles by the occasional passage of bougies. This question of mechanical stretching, however, does not enter into the technique of Doumer's method as I have conceived it. The diameter of my electrodes is, in the first place, too small to produce mechanical stretching, and, in the second place, as I ought, perhaps, to have stated in my original communication, it is quite unnecessary to employ any force in introducing an electrode. One of the most striking early effects of the current is the disappearance of any existing spasm, so that after a minute or two a suitable electrode will slide through the sphincters almost by its own weight.

2. Mr. Mummery claims better results than mine for the routine treatment as applied at St. Mark's Hospital to acute or recent cases. I do not know what his figures actually are but I have apparently been too modest in my claims. Of the 25 acute or recent cases quoted, 14 were anatomically cured, nine others might be described as clinically cured—as they are still practically free from any local discomfort—and of the remaining two cases I may say that the abandonment of treatment was not due to any doubt as to its success.

3. I can assure Mr. Mummery that there is not any risk of the causation of either electrical or x-ray burns at the hands of anyone qualified to employ high-tension currents in medical work; neither can I see that I have made any such admission. Electricity, like any other branch of medicine or surgery, requires experience and it is not fair to judge of the risks attending its use by beginners.

4. As regards the treatment of fissure my experience shows me that the introduction of an electrode made of glass or polished metal causes far less pain than that accompanying a digital examination. In the first place, the current has a decided anæsthetic action when properly applied, and, in the second place, there is no necessity in such cases to employ a large electrode. The diameter which I most usually use varies between about three and 15 millimetres.

I am still of opinion that, both for the good local results obtained and also for the incidental beneficial effect on a patient's general condition, the method of treatment as described by me gives results superior to any other non-operative method with which I am acquainted.

I am, Sirs, yours faithfully,
T. J. BOKENHAM.

Devonshire-street, W., July 19th, 1904.

KADER'S OPERATION OF GASTROSTOMY.

To the Editors of THE LANCET.

SIRS,—I am glad to be able to add another case of this operation to the four recorded by Dr. J. C. Renton in THE LANCET of July 16th, p. 144. I performed this operation for stricture of the œsophagus in the Lincoln County Hospital on June 8th and the result has been most satisfactory. There is not the slightest regurgitation and the patient is able to pass a soft tube and to feed himself with great ease. The operation is simple, quickly done, and *appears to answer its purpose excellently.*

I am, Sirs, yours faithfully,
WM. HY. B. BROOK, F.R.C.S. Eng., M.D. Lond.,
Surgeon to the Lincoln County Hospital.
Lincoln, July 22nd, 1904.

THE USE OF PHENYLHYDRAZIN IN THE CLINICAL EXAMINATION OF URINE.

To the Editors of THE LANCET.

SIRS,—In a communication under the above heading, published in THE LANCET of July 23rd, p. 211, Dr. W. H. Willcox details certain experiments he has carried out with a modification of a portion of a method I have employed as an aid to diagnosis. To enter into a detailed criticism of his conclusions, and the experimental evidence on which they are based, is not feasible in the space afforded by a letter. I shall therefore reserve my remarks for a paper in which I hope to clear up certain misapprehensions that appear to exist and to give further details of my work. I would, however, point out that Dr. Willcox's experiments, and consequently the results he has obtained, differ materially from mine, and also that I am not aware that anyone competent to express an opinion has stated that "the production of characteristic yellow crystals in a urine after hydrolysis with hydrochloric acid" is a "specific test for any special pathological condition."

I am, Sirs, yours faithfully,
Beaumont-street, W., July 25th, 1904. P. J. CAMMIDGE.

ONE FORM OF SUPPURATIVE APPENDICITIS.

To the Editors of THE LANCET.

SIRS,—The paper by Mr. A. C. Roper in THE LANCET of July 23rd, p. 212, on One Form of Suppurative Appendicitis, is of great interest and raises points of considerable practical importance. That it is possible for caseous tuberculous mesenteric glands to set up symptoms simulating appendicitis I have no doubt. During the last few months I have made necropsies on two cases in which this occurred. One was in a young man, aged 20 years, who was apparently in good health until a few months before his death, when he had an attack of pain in the right iliac fossa with sickness and distension. It subsided in a few days and he went on well until a second attack with marked swelling in the right flank. An operation was performed but the patient died from general peritonitis. At the necropsy the abdominal mesenteric glands were found to be enlarged and caseous, especially about the cæcum. No other tuberculous lesion was discovered. The second case was in a little girl, aged three years. She had no previous illness to call attention to her condition until the symptoms which were diagnosed as "appendicitis." An operation was performed and an abscess was found in the right iliac region. She also died from general peritonitis and at the necropsy a mass of enlarged caseous mesenteric glands was found in the neighbourhood of the cæcum, one of these being merely a bag of calcareous débris. There was no evidence of tuberculosis in any other organ.

That these two cases were both tuberculous is fairly certain and from what I infer from reading the account of Mr. Roper's three cases it seems likely that they were of similar origin, especially as two of them occurred in young children.

I am, *Sirs, yours faithfully,*
University College, Sheffield, July 25th, 1904. ARTHUR HALL.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The New Welsh Waterworks.

THE great engineering undertaking authorised by Act of Parliament in 1892, commenced shortly afterwards, and now practically concluded at a cost of something like £6,000,000 up to date, was set in operation on July 21st, when His Majesty the King visited Rhayader and turned on the tap which admitted the first stream of water to the filter-beds and on the same occasion knighted, to the great satisfaction of all the citizens of Birmingham, the very popular and most efficient Lord Mayor, Mr. Hallewell Rogers. This is not the place to give any account of this huge undertaking but *the following figures extracted from the special* account [illegible] *y Post* will give some ide[illegible] of the amount of water [illegible] storing :—

Reservoir.	Capacity.	Water area.	Height of dam.	Top water level.
	Million gallons.	Acres.	Feet.	Feet above O.D.
Caban Coch	7540	497	122	820
Pen-y-Gareg	1320	124	123	945
Craig Goch	2000	217	120	1040
Dol-y-Mynach ...	1500	148	101	900
Cil Oerwynt	3100	269	109	1095
Pant-y-Beddau ...	1900	244	93	1175

The water is conveyed to Birmingham through an aqueduct 73½ miles in length and the fall over that distance is only 170 feet, just enough to keep the stream of water steadily flowing. It takes 48 hours over its journey. The brunt of the work in connexion with the business side of these operations has fallen on the shoulders of the chairman of the water committee, Alderman Lawley Parker, and the citizens of Birmingham and of the other districts served by this supply should always feel grateful to this gentleman for the untiring and unselfish manner in which he has devoted nearly the whole of his time, for the past ten years, to the enormous task which has been laid upon him. One can hardly help feeling a twinge of regret that some mark of recognition was not awarded to the man to whom, more than to any other, the success of the undertaking is due.

Hospital Sunday Fund.

A very important change in the method of allocating this fund has just been decided upon. In the past the funds accruing have been given on one year to the General Hospital, on the second to the Queen's Hospital, and on the third to the amalgamated charities—i.e., to the remaining hospitals and institutions of like character in the city. Each institution or group, therefore, "came into benefit," so to speak, once in three years. At the recent annual meeting of the friends and supporters of the fund it was proposed by the Lord Mayor that in future the Hospital Sunday collection should be divided annually amongst all the charities participating, it being understood that the division should be in the same proportion as the present—namely, one-third to the General Hospital, one-third to the Queen's Hospital, and one-third to the amalgamated charities. In seconding the motion, which was ultimately carried unanimously, Alderman Beale said that it must make a stronger *appeal to the people of Birmingham to feel that* for the whole of the charities without distinction a particular Sunday was set aside as a day of collection, and possibly as a day upon which so many of the public who had not experienced a day's illness during the year might think of those who had not been so fortunate. He was hopeful that if ministers would point out to their congregations the change which had taken place there would be an improvement in the fund which they all knew to their great regret had been practically standing still for the past 40 years. It was time some movement was made. Other funds had grown with the growth of the town; this for some reason had stood still.

Training of Midwives.

A largely attended meeting of ladies has recently been held to discuss this matter. The Lady Mayoress, who presided, said that it was most important to secure a sufficiency of properly qualified midwives and expressed the hope that the scheme of the Lying-in Charity would be liberally supported. The management committee had purchased a site in Loveday-street for a maternity institution and a fund of £5000 was now wanted for the erection of the building. It was a lamentable fact that 60 per cent. of the births in Great Britain were not attended by medical practitioners and among the poorest classes that figure was increased to 80 per cent. It was of the utmost importance that adequate provision should be made for skilled nursing for the poor married women of the city, especially having regard to the demands of the legislature in reference to the qualifications of those who undertook this responsible work. Mrs. Wallace Bruce said that under the new Act the registration of midwives was compulsory. She spoke of the pitiful tragedies which were exposed at the coroner's court as a result of the ignorance of midwives and pointed out that the coroner had no power, although the deaths were due to ignorance, to stop these nurses continuing their work. About two-thirds of the blindness of people were due to negligent treatment at birth, while statistics showed that lunacy and disease were due to an appalling extent to the same cause. Miss Gibson, matron of the Birmingham City Infirmary, urged that what was needed in Birmingham was not monthly nurses but midwives. There was at present no place where the midwife, as such, could be trained in the city. A number of subscriptions were announced at the end of the meeting, including one of £500 from a lady who did not wish her name to be made known.

Birmingham and Midland Eye Hospital.

The annual meeting of the friends of this charity has recently been held under the presidency of Viscount Cobham. Both the annual subscriptions, which amounted to £4350 6*s*. 6*d*., and the donations (£705, including £500 from the Hospital Saturday Fund) showed an increase upon the last year. The total payments, on the other hand, showed a decrease of £219 as compared with the past year, the expenditure having been £7580. The legacies for the year amounted to £2800 as compared with £930 in 1902. The total number of patients treated, exclusive of those on the books at the commencement of the year and of renewals, had been 24,381, the out-patients numbering 23,434. The medical report showed that 682 operations were performed upon in-patients, including 263 for the removal of cataracts of various kinds and of these ten proved unsuccessful. 75 useless or dangerous eyes were removed. This hospital can certainly be congratulated upon its financial position, so different from that of most, if not all, of its sister institutions in the city, since it carried forward a balance of £8237 this year, including a balance from the previous year of £6000. In moving the adoption of the report, Viscount Cobham expressed the fear that many charitable institutions, if deficits continued, might have to come upon the rates, which, in his opinion, would be a very disastrous thing from the point of view of the administration of the institutions and also from the point of view of charity itself. The Eye Hospital does not seem to be in any danger of this fate.

The Blind Institution.

Very different was the tale told at the annual meeting of the supporters of the Blind Institution held on the same day and presided over by the same chairman. The report stated that the number of blind persons directly benefited by the charity during the past year amounted to 634 and exceeded the total of the past year by 19. The education of the blind pupils at the present time presented exceptional difficulties since there was an unusually large percentage of children in the school who suffered from bodily and mental defects as well as from blindness and this necessitated a large amount of individual and special tuition as well as great resourcefulness on the part of the teachers. The Education Act of 1902 gave permissive power to the authorities to pay for the education of the blind after the age of 16 years, the limit beyond which payments could not be made under earlier Acts. A number of authorities had been approached and had consented to pay a portion of the fees for pupils beyond the age mentioned. With regard to the trading department it was pointed out that its primary object was to provide suitable occupation for blind persons, so that they might be enabled to maintain themselves by honest industry. The sale of goods during the year amounted to £8441, as compared with £2486 in 1894. The number of blind workers had increased from 19 in 1894 to 66 in 1904. The wages had risen during the same period from £419 to £2245. Boot mending and stocking knitting had been added to the list of trades taught in the institution. The finances were still in a very unsatisfactory condition. There were a deficit on the general account for the past year of £1256 and an accumulated adverse balance of £477 on the adult blind branch account. The committee had employed every legitimate means to increase the income but the result was not adequate to the need. It was announced that the kindergarten school was approaching completion and would be opened in September. The donations towards this branch of the work amounted on March 31st to £13,493 but a sum of £4000 must still be raised if the school was to be opened, as was desirable, free from debt.

July 26th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Royal Infirmary.

AN amended plan of the infirmary is to be submitted to a meeting of the trustees to-morrow. There is no alteration proposed as to the front elevation to Oxford-road. The official and administrative, the teaching and residential portions of the hospital will occupy this front. The Nelson-street frontage, which runs at a right angle to Oxford-street, will be devoted chiefly to the out-patients' department and in it will be the entrance for all patients. There is a back street, Berlin-street, which will be used for all the purposes for which a back entrance is required, while on the fourth side there will be an entrance for hearses into a closed and covered yard. This fronts to York-place and it seems unfortunate that the hearses must come and go on that side. It will not increase the amenities of that locality and it might surely have been arranged for this sad but necessary work to be carried out in Berlin-street. The medical and surgical wards are arranged in two sets of four parallel pavilions with south balconies overlooking the gardens of the hospital. All the pavilions form self-contained units, each medical ward with day and lecture rooms, physicians' rooms, &c. The surgical pavilions have operating theatre, day-rooms, &c., complete. All the pavilions are connected by glass-covered ways so designed as to isolate each in the event of fire, while there is practically no obstruction to the free passage of air "through and around" every block. The pavilions run north and south and each is separated from its neighbour by about double its height. "Each has also its separate garden with access from each floor for patients." To the extreme south-east is the isolation pavilion, while to the south-west is the pathological department with lecture theatre, mortuary, &c. The total accommodation at present provided will be 481 beds, but an addition of 108 is contemplated which will make a total of 589. The buildings will be lighted by electricity and the various lifts will also be worked by it. The heating will be chiefly by hot water under forced circulation, coal fires being used as little as possible. The buildings will be of red brick with Portland stone. The question of a receiving-house in the centre of the town and of an out-patient department there has been a good deal discussed. The committee of the Manchester and Salford Sanitary Association forwarded a resolution a short time since hoping that some provision would be made on or near the present infirmary site for an out-patients' department and for the reception and treatment of emergency cases, and similar resolutions have been sent by the committees of the Manchester and Salford Hospital Sunday and Saturday Fund and of the Red Cross Society. At the board meeting yesterday the chairman, Mr. W. Cobbett, stated that no decision had been arrived at and such decision could only be a recommendation to the trustees and must come before them at a special or annual meeting. As the removal to Stanley-grove would not take place for some four years there was no necessity, he said, for an immediate decision.

Child Mortality at Burnley.

Some of our Lancashire towns stand out in an unhappy and discreditable prominence from their high mortality, especially as regards the children. Among them Burnley at present heads the list with an infantile death-rate of 217 per 1000, the highest of the 67 large towns of England and Wales, the next highest being another Lancashire town, Wigan, with 180. In the third quarter of last year the infantile death-rate of Burnley rose to the grievous proportion of 251 per 1000. This loss of human life goes on year by year without attracting any very deep or widespread attention and with little apparent check from sanitary or philanthropic efforts. If one tries to ascertain the cause many factors are found to be at work. There are the smoky, dirty atmosphere of our manufacturing towns, the still worse air of the close and stuffy rooms in which so many live, the want of the mother's care while she is in the mill, where she goes as soon after her confinement as she is able and before she is fit to work, and the want of the mother's milk and the substitution of all sorts of unsuitable food by those who have the so-called charge of the child, sour milk from a dirty bottle being one of the least harmful. "Much of this preventable suffering and waste of life arises from ignorance which seems as dark as ever among a large proportion of our working women, while its dispersion by our elementary, so-called, education seems as hopeless as ever, thou[illegible] the educational dry [illegible] There is also another [illegible] than we like to admit—i.e., the little value attached to infant life even [illegible] people." It is il[illegible] of which I can v[illegible] domestic life of "Mary Anne" and the advent of her last baby as increasing her troubles and cares, for there were seven or eight children already, when one benevolent old woman said, "It would be a blessed good thing if it would please the Lord to take three of the littlest."

Pollution of the Irwell.

At the Bury police-court on July 21st the Radcliffe urban district council was proceeded against for sending liquid sewage into the Irwell. The works are insufficient and three inspectors found on June 3rd at midnight that "seven out of the eight tanks were running off into the river full and the eighth was being filled." This, of course, meant that [illegible] preparing efficient schemes.

The Water-supply.

The recent fine weather has caused large demands on the water-supply. On Tuesday last the consumption is said to have b[illegible] city, the quantity being [illegible]ek before last the daily [illegible]9,000,000 gallons, 5,500,000 gallons in excess of that used in the corresponding period of last year. At the end of last week the stock of water should last for 64 days at an estimated daily consumption of 34,000,000 gallons.

Public Baths for Moss Side.

Moss Side, which may be said to be in Manchester, though not of it, having an independent existence, proposes to spend £10,000 on public baths. So far the district has had to depend on those of Manchester, the nearest of which are about one and a half miles away. There are to be a swimming bath 75 feet long by 30 feet wide and 32 slipper baths, 20 of which are to be for men. The period of her isolation will, however, soon be over as in November next the Moss Side district is to become amalgamated with the city. In view of this the plans have been submitted unofficially to the baths committee of the city council. It is to be regretted that no washhouses have been provided on the ground "that the district was not of a character to need them"—i.e., that it was a little above the need of washhouses, if not of baths. There are, however, plenty of poor women in Moss Side to whom a public washhouse would be a boon of great value. It is difficult to understand the apparent reluctance to provide public washhouses in poor districts. They are valuable in more ways than one. It is evident that where the washing and drying of clothes are carried out away from the dwelling or perhaps the room occupied by a family the home will be more comfortable for the husband on return from work than if it were pervaded by steam and the smell of soapsuds and that he will be the less likely to adjourn to the public-house or the "vaults" that are sure not to be far off.

Unhealthy Carriages and Tramcars.

The efficient ventilation of our railway carriages and tramcars has not yet been accomplished and it seems as if the difficulties in the way were so great as to check rather than to stimulate efforts for overcoming them. One difficulty as to railway carriages arises from the morbid susceptibility to draughts and chills (and the consequent aversion to fresh air) of the young men who crowd the trains for the suburbs after the business of the day is over. Nothing is commoner, at all events in the neighbourhood of Manchester, than to see a compartment with both windows closed full of young [illegible] get in as they get out, even a [illegible] will find the air of the carriage [illegible] to be endured. And on the whole the first-class carriage is the worst. When one sees this arrangement for air poisoning, of which the gauntlet is run regularly twice a day, and remembers that the intervening hours have in most cases been passed in an ill-ventilated warehouse, the counting-house of which is generally the worst ventilated of all, it is not to be wondered at that most of these young men look weakly and anæmic and that too many of them die prematurely from consumption. At the meeting of the Salford council the other day Mr. Pinder, a member of our profession, drew attention to the bad ventilation of the street cars. Improvement had long been promised and he thought the time had come for these promises to be carried out, as it was important for the health of the public. The present system, he said, "was crude and the inside of the cars contained a poisonous atmosphere, while the odour, especially in the hot weather, was appalling." Another of the councillors suggested that "if the motor-man would only open the door of the car at the terminus a little fresh air might get into the car before it started its journey; but he seemed afraid of opening the door." Mr. Pinder proposed a motion, which was carried, that the tramways committee should be instructed to furnish the cars with an efficient system of ventilation May success attend its efforts, for they are needed.

July 28th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

The Housing Problem in South Wales and Monmouthshire.

THE prosperity of the mining industry in certain parts of South Wales and Monmouthshire has created problems in the housing question which have not arisen in other localities. When the colliery districts were being opened out some 40 or 50 years ago it was the custom for the colliery proprietors to provide houses for their workmen in proximity to the workings. In some instances these were one-storeyed wooden cottages and in other cases more substantial structures of brick or stone were erected. Later private speculation and building clubs sufficiently met the wants of the rapidly increasing population but during the last eight or ten years a scarcity of houses has been apparent in many districts owing partly to the increased cost of building and partly to the fact that private speculators were afraid to risk their capital in localities where the closing of a colliery renders the surrounding house property valueless. A very large number of houses have thus come to be occupied by more than one family and in many others single men are taken as lodgers. The sanitary officials are often reluctant to take steps to close uninhabitable houses because the occupants cannot find others more habitable. Many sanitary authorities appear at last to be realising that they must remedy what is recognised as a serious and growing evil. The Merthyr urban district council has erected 100 cottages between Merthyr and Dowlais and the undertaking appears so far to have been successful. The Ogmore and Garw urban district council has decided to build 100 houses in two different parts of the district at a cost of £175 per house. This decision has been arrived at owing to strong representations having been made by the South Wales Miners' Federation which pointed out that a large number of houses with only [illegible] loan of £6150 for the purpose of erecting workmen's houses and a tender has been accepted for the building of 28 houses at £200 each. The Bedwellty urban district council, after meeting with some opposition, has decided to build 16 cottages at New Tredegar, each with three bedrooms.

The Western Counties Branch of the British Dental Association.

The annual meeting of the Western Counties branch of the British Dental Association was held at Frome, Somerset, on July 22nd under the presidency of Mr. A. G. Hayman who gave an interesting address on the Progress of Dental Surgery. Papers were read by Mr. L. L. Smith on Different Methods of Treatment for Live and Dead Pulps. Mr. R. Willcox contributed Notes on Treatment of Exposed Pulps by Anæsthesia produced by Local Pressure, after which a demonstration was given by Mr. W. de C. Prideaux on Bœsch's Anchors for Porcelain Inlays. In the evening the dinner was held at the George Hotel when several members of the medical profession were present.

The Cornwall County Nursing Association and the Midwives Act.

Lord Mount-Edgcumbe in a letter to the local press draws attention to the subject of the registration of the nurses of the Cornwall County Nursing Association under the Midwives Act. He states that as a result of a meeting of members of the association and medical men it was resolved that if the County Nursing Association would make rules to insure that its nurses are not to attend a confinement without a medical man in cases where the total earnings of the patient's household exceed 30*s.* weekly and that the nurses should never interfere with the patient's selection of her medical attendant there could be no objection to the nurses being registered and practising under the Act; all the village *nurses of the association are holders of the certificates of* the London Obstetrical Society. Lord Mount-Edgcumbe adds that the committee will meet on July 30th when the matter will be finally settled, and he is anxious in the meantime that members of the medical profession should clearly understand how the association has tried to solve this difficult subject.

Shell-fish and Enteric Fever.

At the meeting of the St. Thomas's rural district council held on July 16th the medical officer of health, Mr. M. Farrant, reported two cases of enteric fever contracted from eating cockles. The medical officer of health of Torquay (Dr. T. Dunlop) has issued notices urgently advising the inhabitants of the town and neighbourhood to refrain from eating cockles and mussels. He states that most of the shell-fish sold are collected from beds of rivers into which large quantities of town sewage are poured and consequently the risk of carrying germs of disease to the consumer is very great.

Geological Model of Bath.

The medical officer of health of Bath (Dr. W. H. Symons) has completed an excellent geological model of the city of Bath and the surrounding district, covering an area of 36 square miles. The horizontal scale is six inches to the mile and the vertical scale is six inches to 1000 feet. The model has been placed in the museum of the Royal Literary and Philosophical Institution and it will no doubt be consulted with advantage by intending residents in the city.

University of Edinburgh Graduation Ceremonial.

ON July 23rd the summer graduation ceremonial of the University of Edinburgh was held in the M'Ewan Hall. The Vice-Chancellor, Principal Sir William Turner, presided. There were five recipients of the honorary degree of Doctor of Laws—namely, Samuel Henry Butcher, Litt.D., LL.D., lately professor of Greek in the University of Edinburgh; the Hon. Sir Walter Francis Hely-Hutchinson, G.C.M.G., Governor and Commander-in-Chief of the Cape of Good Hope; the Right Hon. John Morley, M.P., P.C., O.M., F.R.S., LL.D., D.C.L.; Sir George Reid, LL.D., D.L., lately President of the Royal Scottish Academy; and Professor William Thomson, M.A., B.Sc., Registrar of the University of the Cape of Good Hope. The degree of Doctor of Medicine was conferred on 59 graduates. Three candidates obtained gold medals—namely, Thomas Lowe Bunting, M.B., C.M., 1889, for a thesis on the Histology of the Lymphatic Glands; John Cameron, D.Sc., M.B., Ch.B. (with second-class honours), 1898, for his thesis on the Development of the Retina in Amphibia, an Embryological and [illegible] illiam Hogg Prentice, M.A., M.B., [illegible] honours), 1901, the title of his thesis being "Some Notes on the Action of African Cobra Venom." Two candidates obtained the degree of Bachelor of Medicine and Master in Surgery, while the degree of Bachelor of Medicine and Bachelor of Surgery was conferred on 124 candidates of whom nine were women. Professor D. J. Cunningham, F.R.S., Promoter of the Faculty of Medicine, delivered t [illegible] subject being the [illegible] At the close of t [illegible] nded a reception i [illegible] s entertained to luncheon in the union dining-room, Mr. A. F. Whyte, president of the union, being in the chair. In the course of the luncheon speeches were made by Mr. John Morley, Sir Walter Hely-Hutchinson, Professor Thomson, and Emeritus Professor Butcher.

Royal College of Physicians of Edinburgh.

A quarterly meeting of the Royal College of Physicians of Edinburgh was held on July 19th, Dr. T. S. Clouston, the President, being in the chair. The President made feeling reference to the loss which the College had sustained by the death of Dr. Peter Young, a Fellow of the College. Harry Oliphant Nicholson, M.D. Aberd., was introduced and took his seat as a Fellow of the College. On a ballot the following candidates were admitted to the Membership of the College after examination: James Cameron, M.D. Edin., Edinburgh; George Douglas McRae, M.B., C.M. Edin., Edinburgh; Alexandre da Fonceca Dias, L.R.C.P., L.R.C.S. Edin., Edinburgh; Theodore Charles Mackenzie, M.B., Ch.B. Edin., Edinburgh; and Thomas Garnet Stirling Leary, M.B., Ch.B. Edin., Castlederg, Tyrone. The Registrar reported that since the last quarterly meeting 31 persons had obtained the licence of the College by examination. The regulations regarding the single licence and membership and fellowship of the College for the ensuing year and the regulations for the triple qualification were approved. The Hill Pattison-Struthers bursary in clinical medicine, which is in the gift of the College, was awarded after examination to Mr. James Watson. With regard to the proposed institution of an academic dress distinctive of licentiates of the College, it was resolved to delay consideration of the matter.

City of Glasgow Fever Hospital, Ruchill.

Dr. Alexander Johnston, physician and superintendent of this hospital, recently submitted to the committee on health the report of the hospital for the year ending May 31st, 1903. The number of admissions for the year amounted to 2047, whereas for the two preceding years they numbered 3012 and 2251 respectively. This represents, says Dr. Johnston, the comparative scarcity of infectious diseases in the city of Glasgow. The general mortality-rate was 8·8 per cent. Nearly 60 per cent. of the new patients admitted were under ten years of age. The number of cases of scarlet fever numbered 847, or 41·2 per cent. of the total admissions. 21 of these patients, or 2·4 per cent., died, the lowest mortality rate on record in the history of the City of Glasgow fever hospitals. The cases of diphtheria numbered 215, with 42 deaths. The mortality rate of 19·5 per cent. was the highest yet recorded in Ruchill, but of the fatal cases 20 were admitted moribund. 246 cases of enteric fever were admitted of which 45 died, giving a mortality rate of 18·2 per cent. The number of cases of measles was 159, the death rate being 6·2 per cent. The deaths from this disease were almost all due to pulmonary complications, and no death was recorded of any patient over ten years of age.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Dispensary Medical Officers.

THE latest device to deprive the unfortunate dispensary medical officer of one of his few remaining privileges has recently been put in practice at Kinsale. Hitherto, where a medical officer was able to obtain a month's holiday, he was permitted to choose as a substitute some friend or neighbour to whom he could intrust not only his public duties but also the charge of any private patients whom he chanced to have in his district. Now, the boards of guardians have apparently determined to nominate for themselves as a locum-tenent any man whom they choose to elect as their favourite. It seems tyrannical. At the last meeting of the board of guardians of the Kinsale union

on July 20th Mr. W. G. Meade was given four weeks' leave. He recommended Mr. J. Keating, whose district adjoined, as his substitute, but the guardians insisted on appointing another man from the neighbourhood, whereupon Mr. Meade withdrew his
if he could not choose h
pensary duties with also t
if, in fact, he could not go away on his vacation comfortably, he would prefer to remain at home. At the same meeting Mr. A. O'Leary recommended Mr. J. Shorten, whose district adjoins, as his temporary holiday substitute. The guardians, however, proceeded to appoint a local practitioner whom they selected. Mr. O'Leary took the same view as Mr. Meade, with the result that both medical officers withdrew their applications for leave and elected to remain at home. The situation seems disgraceful and one is inclined to ask, Where is the Local Government Board? As to the grievance in reference to salary, at the meeting of the Bantry guardians held on July 19th, Mr. Bennett of Bantry appeared before the board as the representative of the Irish Medical Association and asked the board to fix the salary for the district of Glengarriff at a higher amount than £100 a year, as it would be impossible for any medical man to live in that backward district where there
an income.

Dublin Sanitary Association.

The council met on July 21st at the offices of the association, the President occupying the chair. The progress of the outbreak of measles in Dublin was traced by a reference to the Registrar-General's weekly returns. It appears that *on Saturday, July 9th, there were 83 cases of this disease* under treatment in the Dublin hospitals and on Saturday, July 16th, there were 77 cases. During the week ending July 23rd ten deaths were registered from measles, the numbers during the preceding three weeks being one, two, and two respectively. The following motion was adopted unanimously:—

ses should be
ing those sick

New Medical Magistrate.

The Lord Chancellor has appointed Mr. John F. Sydney Colohan of Blackrock a justice of the peace for the county of Dublin on the recommendation of the Right Hon. the Earl of Meath.

The New Royal Victoria Hospital, Belfast.

Those who make a study of hospital construction, and especially of the much debated question of heating and ventilation, will be interested to learn some facts as to the working of the plenum system in the new Royal Victoria Hospital, Belfast, which was opened by His Majesty the
work of heating and ventilating
e has been very successful. The
in the open air in the neighbourhood of the hospital was 22° F., while inside the institution the average temperature was kept at from 59° to 62°. The average weekly consumption of coal during the winter was 45 tons. This fuel is used to heat the boilers which provide the steam for the engines which work the great fans of the plenum system. This steam is also used to heat pipes which warm the air; it is likewise employed for sterilising

with the plenum system. During the present summer the highest temperature so far has been 124° in the sun or 79° in the shade, while at the same time the
wards was 65°. The average temperatur
been from 63° to 65°, with an outside he
the summer the average consumption of
18 to 20 tons per week. In the winter one
but in the summer it has been found necessary in order to keep the wards cool to have the two fans going, because in this way the air is changed in the wards ten to 12 times in an hour. In the winter it was found sufficient to change the air seven to eight
hour and one fan was enough to do
been kept in action since June 1st

the second fan, the engine being so constructed that it is underloaded with one. In the lofts above the engine house there are tanks of water with an automatically-regulated overflow, so that in winter 15 gallons flow over three screens
washed every ten minut
over six screens every
screens are "hosed" every second day and the main air duct washed out once a week, so that as a result the air as it enters the wards is deprived of impurities and leaves no trace of discoloration.—Lord Dunleath, who is closely connected by family ties with Belfast, has given £1000 to the Royal Victoria Hospital to endow two beds, "The Dunleath Beds," in the Mulholland Ward, which was named after his grandfather, the late Mr. Andrew Mulholland. It is hoped soon that another unit—that is, 32 beds—will be opened.

Ulster Branch of the British Medical Association.

For the session 1904–05 Professor J. A. Lindsay has been elected President, Dr. Cecil E. Shaw secretary, and Dr. J. S. Darling (Lurgan) treasurer.

Action against a Medical Man.

A case which
occasioned a c
and medical cir
consequently t
from commentin
simply state the facts. The action was brought by Alfred Ernest Tughan, a minor, by his father, against Mr. C. K. Darnell of Bangor, co. Down, to recover £250 on account of personal injuries alleged to have been sustained by reason of the negligence *of the defendant. A very strong* bar was *engaged on* each side, the defence being in the hands of the Medical Defence Union. It appears that the young gentleman, Mr. Tughan, the plaintiff, who is just over 17 years of age, had been suffering from mumps in Belfast and on recovering was taken to Groomsport, a seaside resort near Bangor, on Belfast Lough, and that while there he developed the rather rare complication orchitis as a sequela of the mumps and Mr. Darnell was on April 4th called to see him. Mr. Darnell explained what was wrong and wrote two prescriptions, one for internal medicine and the other for external
arisen.
and, acc
to be sp
part until April 9th. Half a yard of lint was ordered together with half a pound of absorbent wool for a cushion. The mother applied the liniment with the result that the skin became blistered and belladonna poisoning set in. Mr. Darnell had in the meantime left home and the plaintiff's father employed other medical men—one in Bangor and two from Belfast, one of these being his brother-in-law. For the defence it was contended that the defendant specifically directed that the liniment was to be used only in case pain arose and his case was that the wrong use of it by the boy's mother did the harm. Further, Mr. Darnell swore that he told the plaintiff's father that he was leaving home for a few days and that if the boy was not so well his father was to get any of the other medical men in Bangor, and when Mr. Darnell's wife was told that the boy was ill she sent a local medical practitioner to see him. The Belfast consultant who saw the boy with this Bangor practitioner was not called by the plaintiff. For the defence several medical men were called, their evidence supporting the contention that the treatment as directed by Mr. Darnell was correct. The judge in an impartial summing up left the case to the jury who after an absence of an hour and 15 minutes announced that they had not agreed and as the foreman said in reply to the judge that there was not the slightest chance of their agreeing they were discharged.

Destruction of Mosquitoes.

SEVERAL parts of Paris are so infested with mosquitoes that at a recent meeting of the Conseil d'Hygiène et de Salubrité de la Seine a report on methods by which they might be kept in check was considered. The following is a summary of the conclusions which were adopted. In the first place stagnant water where their eggs are hatched and localities where the insects collect, such as cellars, sewers, and dark places, ought to be kept under observation. It was necessary to have regular inspections of drains and sewers of all kinds and of the openings of the pipes which supply water in the streets, to avoid collections of stagnant water, and where insects assemble in numbers to them either by a burning torch or by lime-w. Stables and privies ought to be kept very clean, roofs and rain-water gutters ought to be examined, and water ought not to be allowed to lodge in the gutters. Nothing capable of holding water should be placed in front of windows and places which are the haunts of mosquitoes should be well ventilated. Stagnant water should not be allowed to remain in gardens and courtyards. Fountains and basins in public places should be emptied and cleansed at least once a week and plenty of fish should be kept in large sheets of water. In basins and casks standing on private ground there should be a layer of petroleum oil on the surface of the water (about a gramme per square metre) or if the water contains fish a layer of salad oil. The public should be advised to use mosquito curtains. Mosquito bites should be treated with a drop of tincture of iodine or with a drop of a solution of guaiacol of 1 per cent. strength.

Lactation and Pathogenesis.

At a recent meeting of the Academy of Sciences M. Charrin and M. Vitry said that lactation was generally considered to be capable of producing in the organism a series of changes more or less favourable to the development of disease and experiments made by them had shown the nature of these changes. In a guinea-pig which was in milk the convulsions brought about by a dose of strychnine were both earlier and more intense than those due to the same dose administered to a guinea-pig which was not in milk; death was sometimes even caused by doses which were not fatal to the control animal. The power of resistance to infection was similarly weakened; a dose of a culture of bacillus pyocyaneus which would cause only a temporary lesion in the control animal might prove fatal to an animal giving milk. This diminution of resisting power was partly due to the attenuation of the antitoxic protective substances and more particularly to the diminution of the antitoxic power of the liver. A piece of normal liver left in contact with a solution of nicotine weakened it more than an equal weight of liver substance taken from an animal giving milk. If to these causes were added hyperglycæmia and fæcal retention it would be seen that lactation predisposed to disease by accumulating organic poisons, by diminishing the natural powers of resistance to such poisons, and in establishing conditions favourable to infection; it, in fact, prolonged the dyscrasiæ associated with pregnancy.

Public Medical Service in Madagascar.

At a meeting of the Academy of Medicine held on July 12th M. Kermorgant communicated some particulars taken from a report presented by General Gallieni relative to the working of the medical and public health services for natives (*assistance médicale et de l'hygiène publique indigène*) in Madagascar during 1903. On Jan. 1st, 1904, the service received the important addition of a school of medicine to which was attached a native hospital, a Pasteur institute at Tananarive, a station for the production of vaccine lymph at Diégo Suarez, a central pharmacy, 129 hospitals containing 1867 beds, ten dispensaries, 17 stations for midwives, and seven leper hospitals. The hospital of the colonial service and certain private establishments also gave assistance. The medical service leaves nothing to be desired in the provinces of the central plateau; the total outlay on it was 1,019,042 francs (£40,760); 16,788 persons have been treated in the hospitals; 3079 lepers have been isolated; 1,023,425 patients have received advice; and 70,991 vaccinations have been performed. There has been a notable increase in the number of cases of malaria, attributable, it would seem, to the fact that after the rice has been harvested the rice fields are again flooded with water instead of remaining dry, as in former years, and the mosquitoes therefore breed more freely. The birth-rate in Madagascar is considerably higher than the death-rate.

Disadvantages of Sterilised Food.

If full-grown animals are kept in a sterile atmosphere and fed on sterilised food their vitality is brought down below that of control animals treated similarly in all respects except that the access of microbes to them is not interfered with. This has been already proved by M. Charrin and at a meeting of the Academy of Sciences, held on July 11th, he gave an account of new experiments which supply an explanation of the phenomena. Proportionally to their weight all the animals received the same quantity of the same sterilised in the same way at 100° C., but carrots for the control animals were dusted over with some of the earth which had previously covered them. In these circumstances, the animals fed on the sterile food generally died in from three to five weeks, predeceasing the control animals. In the few cases in which guinea-pigs after ingestion of microbes died before the others the usual reason was that exceptionally virulent bacteria had been introduced along with the dust. In the animals fed aseptically enteritis with retention of bile and softening of the walls of the ileum was common. The microbes soon became less numerous; those which usually occurred in the intestine were normally in that situation under disadvantageous conditions owing to the presence of phenol, ammoniacal salts, mucus, and competing forms of life, as well as to the scanty supply of oxygen for the aerobic organisms; importations from without, especially those which came with the food, were therefore necessary for keeping up the stock. Cultures made in glass with material taken from the guinea-pigs fed aseptically showed only cocci, the bacilli having disappeared, whereas in the control animals at the same stage of the experiment the latter forms predominated. In the animals fed aseptically albumin was less quickly peptonised and cellulose was less readily attacked than in the others. The nutritional conversion of cellulose and the proteid constituents of the food was diminished in the animals fed aseptically and these substances acted as foreign bodies, membrane and producing symptoms of their consequences. It was therefore plain that some microbes were not only not injurious but were of decided utility and that the conditions in which the sterilisation of food was advisable still remained an open question.

Accidents in Laboratories.

While M. Dubreuil, *agrégé* of the University, was engaged in some researches in the laboratory of the École Pratique des Hautes Études a flask of hydrogen exploded and a laboratory assistant received an injury which resulted in the loss of his right eye. He therefore brought an action for damages against M. Dubreuil and the State. The director of the school, being a public teacher, is legally responsible for the harm done by his pupil M. Dubreuil, and the State being represented by the director is consequently responsible also. The court, however, without controverting this argument, dismissed the claim made by the assistant against the State, but M. Dubreuil was ordered to pay him an annuity of 500 francs.

July 26th.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE.—During the past year there have been 1122 specimens examined in the bacteriological department, showing an increase of 184 over the previous year. The great majority of the specimens are examined for the various county councils and public institutions in the neighbourhood. Out of 650 specimens of sputum examined for tubercle bacilli 39 per cent. were found to be positive. Out of the 223 cases of suspected diphtheria 35 per cent. were found to be positive, whilst from 79 specimens of blood from suspected cases of enteric fever 32 per cent. were positive. The Newcastle water was examined every month, also water for other public bodies. Ten specimens of blood were examined for anthrax with positive results in five cases. Tubercle bacilli were found in urine in five cases out of 39.

THE
BRITISH MEDICAL ASSOCIATION.
MEETING AT OXFORD

THE seventy second annual meeting of the British Medical Association commenced at Oxford on Tuesday last and marked the fourth occasion on which the Association has chosen the university city for its annual meetings Unfortunately the meeting has not been favoured with good weather On Monday afternoon just as visitors began to arrive, a thunderstorm accompanied by torrents of rain broke over the city and rain continued to fall more or less heavily all night On Tuesday the morning was fairly fine but the afternoon and evening were a repetition of Monday Wednesday, again, opened very badly and the rain continued for the best part of the morning The bad weather was the more unfortunate that Oxford is pre eminently a place which needs sunshine to show off its beauties The gardens and groves, such as those of Magdalen New College and Worcester, lose half their charm when visited under a grey dripping sky

The means of getting about in Oxford are of the primitive order, there being only a few horse tramcars and omnibuses with very long intervals between their running The citizens apparently largely rely on their cycles for locomotion and have a fine disregard for the terrors of side slip as they cross and recross the not too well laid tracks in the neighbourhood of the heart of the city Fortunately, cab fares are reasonable with the consequence that the weather has made the cab-driver busy

The service held in Christ Church Cathedral at 10 30 A M on Tuesday was exceedingly well attended The sitting accommodation was in fact strained to the utmost and it was stated that the congregation was one of the largest ever gathered together in the chief church of the diocese The assembling of the congregation was imposing as those wearing academic robes took their places The mayor and his civic staff occupied seats in the choir The Rev the Master of University College preached the sermon The alms, as is usual were devoted to Epsom College and the British Medical Benevolent Fund There was also a special Mass at the Church of St Aloysius at the same hour

On Tuesday evening the President of the Association, Dr William Collier delivered his address in the Sheldonian Theatre The beautiful building (one of Wren s earliest works) was filled by an audience gathered from many a university and by a number of ladies Academical dress was, of *course, worn by those* who had a *right to do so* , but there existed an unfortunate diversity of opinion as to what "academical dress meant and the "use was exceedingly varied Some doctors wore their scarlet gowns either with or without hood, others wore the undress gown with a hood (this, of course, is obviously wrong), and others wore the undress gown by itself However, the general effect was a very charming mass of colour

The proceedings commenced by the Vice Chancellor, Dr D B Monro, welcoming the Association on behalf of the University, and he was followed by the mayor, Mr E A Bevers, M R C S , who performed the same office on behalf of the city The Middlemore prize was then presented to Mr J H Parsons for his researches in ophthalmology, after which the President announced the election of the following gentlemen as honorary members of the Association in recognition of their valuable services in connexion with the meeting The Vice Chancellor of the University of Oxford (Dr Monro), the Dean of Christ Church (the Very Rev Thomas Banks Strong D D), and the Master of University College (the Rev James Franck Bright D D) Then followed the presentation of the distinguished foreign guests and colonial delegates among the former being Professor William Osler of Baltimore, Dr Edmund Landolt of Paris, Professor Hirschberg of Berlin, and *Professor Guglielmo Romiti* of Pisa, while the colonial delegates came from practically every part of the empire Dr Collier then delivered his presidential address, which will be found in another column

It was confidently anticipated, owing to the splendid attractions of Oxford that the attendance of members would be large and this did much to secure an increased application for space in the Annual Exhibition of Foods, Drugs and Surgical Appliances The exhibition was held in two palatial rooms on the first floor of the Examination Schools in the High street, the space afforded was generous and altogether the exhibitors evinced excellent taste in displaying their exhibits On no previous occasion has the exhibition been held under more favourable auspices and although the satisfactory attendance of visitors may be attributed partly to the fact that the reception room and general meetings room were situated in the same spacious building, yet apart from this, there was an evident increasing interest in this important section of the annual meeting

A welcome feature in this year s exhibition was the display of scientific apparatus We have often urged that considerable prestige would be added to this section of the proceedings if some really scientific demonstrations could be arranged It must be admitted that on the whole the annual exhibition wears a business aspect against which, *however nothing can be said so long as* trade is conducted on dignified lines The claims of many new drugs and foods are occasionally pressed with perhaps a little more zeal than the visitor appreciates This is pardonable when the chances which the exhibitor has of actually bringing his specimens under the eye of busy practitioners are considered It cannot be denied however, that the annual exhibition is of decided value to the medical man who means to keep pace with the advances made in pharmaceutical preparations in special foods surgical apparatus and so on All the same it is a relief to him to confront if only occasionally a really scientific demonstration, and the opportunities which have been afforded this year may be noted with satisfaction

Probably the majority of the exhibits could be placed in the category of surgical sanitary, and hospital appliances, and generally speaking perhaps the exhibition had a greater interest for the surgeon than for the physician New drugs, synthetic remedies or methods of administration seemed decidedly less in evidence than has been usually the case In another column the various exhibits are dealt with in some detail and while the convenient classification adopted in previous years is the same, the various sections are taken in a slightly different order in accordance with the scale on which they were represented

In a Convocation held on Wednesday in the Sheldonian Theatre, which was filled with a brilliant gathering, the degree of D Sc , *honoris causa*, was conferred upon the following gentlemen Thomas Clifford Allbutt, M D , F R S , Regius professor of physic at Cambridge , Andrew Clark, F R C S Vice President and chairman of the Council of the British Medical Association , Thomas Dryslwyn Griffiths, M D , late President of the British Medical Association , Jonathan Hutchinson, F R S , late President of the Royal College of Surgeons, Sir William Macewen, M D , F.R.S., Regius professor of surgery in the University of Glasgow; Sir Patrick Manson, K.C.M.G., M.D., F.R.S.; Sir John William Moore, M.D., late President of the Royal College of Physicians of Ireland; and William Osler, M.D., F.R.S., professor of medicine at Johns Hopkins University, Baltimore. The various recipients of the degree were severally introduced to the Vice-Chancellor by the Sedleian professor of natural philosophy, Professor A. E. H. Love, D.Sc.

During the meeting the question of medical defence has been more or less hotly discussed. It has now been finally decided by the representative meeting that the question of medical defence, as submitted to all the divisions of the Association, shall be referred to the original committee that dealt with the question, with instructions that in framing any scheme of medical defence both collective and individual defence should be included. There has been a considerable amount of talk pointing to the idea that medical defence should be provided for members of the Association without any increase of subscription, but the notion has failed to secure sufficient support at any meeting of the members to make it an instruction for the committee concerned with the matter to consider it. This committee, however, has been charged with the duty of stating, in its revised scheme, or statement, to be submitted to the divisions, in what way provision is to be secured for the amalgamation of the existing medical defence societies. It is not to be wondered at that the problem of medical defence has been referred to the committee, nor will this course of events come as a surprise to the most ardent advocates for immediate action.

To many members of the medical profession visiting Oxford Trinity College presented considerable attractions, not only for its architectural details but also for the interest attaching to it as the place where in the troublous times of Charles I. "so great a doctor" (as Aubrey called William Harvey) went "several times to George Bathurst who had a hen to hatch eggs in his chamber, which they opened daily to see the progress and way of generation." William Harvey stayed in Oxford occupied with his researches for so long that the wardens and masters of St. Bartholomew's Hospital placed a Dr. Micklethwayte in his position at that institution, accusing Harvey of having withdrawn himself from his charge and betaken himself to the party in arms against the Parliament. Merton College, however, at that time had a warden named Brent who was accused of absenting himself from his duties for three years, of joining the rebels, and of signing the Covenant. William Harvey was elected warden of Merton College in his place and informed the Fellows assembled in the Great Hall that though previous wardens had most likely joined Merton to enrich themselves he only wished to enrich the College, and he exhorted them to cherish harmonious friendship among themselves. During Harvey's term of office at Merton the College must have presented an animated appearance for its chambers were crowded with officers quartered there and the Queen lodged in the warden's house, occupying the room shown to many visitors this week as "the Queen's Room."

We have again to record our indebtedness to Mr. Guy Elliston, the general secretary of the Association, and to his staff, for the courtesy and much appreciated help extended to the representatives of THE LANCET in several directions.

The seventy-third annual meeting of the Association will be held at Leicester in 1905, Mr. G. C. Franklin, F.R.C.S. Eng., being nominated as President-elect.

THE GENERAL MEETINGS.

THE FIRST GENERAL MEETING.

The first general meeting was held in the Examination Schools, High-street, on Tuesday, July 26th, at 12 noon.

The chair was occupied by the retiring President, Dr. T. D. GRIFFITHS, who, in addressing the meeting, referred in sympathetic terms to the loss sustained by the medical world through the death of Sir John Simon. "We may affirm," he said, "that he has saved far more lives during the last 50 years than all the armies of the world have destroyed during the same period." Dr. Griffiths then proceeded to review the work of the Association during the past year and observed that they had arrived at the close of the first year of their new constitution and the result was fully in accordance with their anticipations. The changes and the alterations were now practically complete, the various divisions, numbering 300 altogether, had settled on their own rules and regulations, and he drew attention to the great advantage accruing from the divisions —viz., that they answer all the purposes of local medical societies. The speaker then drew attention to a further gain attained by the reconstruction of the Association in securing additional power to promote the interests of the profession, to improve public health, and to protect the well-being of the community by guiding and influencing legislation in Parliament. The retiring President then formally introduced the new President, Dr. William Collier.

Dr. COLLIER in taking the chair expressed his thanks to the members for the high honour conferred on him. He soon secured the sympathy of those present by the earnest manner in which he spoke of his duties, whilst his humorous description of the difficulties incident to the meeting of the Association at Oxford put him on good terms with his audience. He hoped, he said, that the members of the Association would not trouble to appear at Oxford in the obsolete garments of conventionality but would revel in light hats, light coats, and light hearts.

Dr. J. H. GALTON proposed, and Mr. W. JONES MORRIS seconded, a cordial vote of thanks to the retiring President which was carried with acclamation.

After Dr. GRIFFITHS had made a suitable acknowledgment, the following gentlemen were elected honorary members of the Association for valuable services rendered to the Association in connexion with the Oxford meeting: Dr. D. B. Monro (Vice-Chancellor of the University of Oxford), the Very Rev. Thomas Banks Strong, D.D. (Dean of Christ Church), the Rev. James Franck Bright, D.D. (Master of University College), and Professor A. G. V. Harcourt, M.A., F.R.S. The chair was then vacated by the President in favour of Mr. ANDREW CLARK, chairman of the Council, who called upon Dr. E. M. Skerritt, the treasurer, to propose that the financial statement for 1903 should be received and adopted. This was duly proposed by Dr. SKERRITT, and after Dr. J. HADDON, Dr. J. BRASSEY BRIERLEY, and Mr. E. H. T. NASH had spoken, and been replied to by Dr. SKERRITT, the motion was put to the meeting and duly carried.

After passing some more or less formal votes the meeting adjourned.

THE SECTIONS.

MEDICINE.

WEDNESDAY, JULY 27TH.

Discussion on the Treatment of Chronic Renal Disease.

After a few introductory remarks by Dr. W. T. BROOKS (Oxford), President of the section, a discussion on the above subject was opened by

Dr. W. HALE WHITE (London) who said that he intended to limit his remarks in the discussion to the consideration of the treatment of chronic interstitial nephritis. So little was known of the pathology of the disease that the treatment fell naturally under two headings: (1) the treatment of particular symptoms; and (2) treatment employed according to the physician's theoretical views on the nature of the disease. Albuminuria was a symptom frequently treated. The mere presence of albumin in the urine was of itself of no importance, except as an aid to diagnosis, as the amount of proteid lost daily in the form of albumin was very small. Albuminuria occurred in heart disease, fevers, calculus, and other conditions, and was never treated in those cases.

The loss of albumin was at most only a few grammes a day and might be compensated for by more in the food. Albuminuria was, however, a very important help to the diagnosis and prognosis of Bright's disease but the records of it were usually of little value as they noted only the percentage and not the total quantity of albumin Not only was the treatment of albuminuria as such unnecessary but in many carefully observed cases a milk diet, which is relied upon to diminish albumin, failed to accomplish this The cardio-vascular system required most notice from the point of view of treatment in chronic renal disease Many patients had a high tension pulse and a hypertrophied heart, in such cases the tension must be reduced by restricting exercise, regulating the bowels, avoiding alcohol, meat extractives, excess of meat food, and the drinking of much fluid Digitalis should never be ordered for such patients In a second class of cases the tension of the pulse was too low and the heart was weak Over and over again physicians forgot that to starve one part of the body involved starvation of the whole, and thus patients kept on a small milk diet in the hope of relieving the kidneys became enfeebled in their general health with consequent cardiac failure Such patients improved on ordinary diet, with a moderate amount of meat and alcohol Some patients were kept too much in bed, with the result that the heart became feeble; they improved when they were allowed to get up On the other hand, many patients took too little exercise and became fat and some drank too much water. In both conditions the work of the heart was unduly increased The physician should endeavour to keep the vascular tension normal without the aid of drugs Œdema in chronic nephritis rarely required treatment except when due to secondary cardiac failure The bowels should be well opened and the fluid ingesta restricted In severe œdema diuretics should be avoided and diaphorectics were of little use. Puncturing the legs with needles or Southey's tubes was the best method of relieving both local and distant œdema, but it should be remembered that no operation required greater care in avoiding sepsis. Turning to the consideration of treatment as influenced by theoretical views of the nature of the disease, substances supposed to irritate the kidney, such as turpentine and cantharides, should never be employed and mercury and lead should never be given for any length of time There was wide divergence of opinion as to the administration of morphine, undoubtedly it checked uræmic convulsions, but it sometimes killed the patient Alcohol was permissible in small quantity when the heart was weak to aid digestion and to promote sleep Patients with chronic interstitial nephritis were often dieted too zealously under the impression that certain articles of food irritated the kidneys, there was no proof of this and no series of cases had been published to show that either chicken, fish, red or white meats were harm[illegible] diet when they loathed the sight of it Tea, coffee, and tobacco should be used in moderation by sufferers from chronic nephritis, as either of these in excess caused a rapid and irregular pulse An excess of water was often given to flush the kidneys and to clear away dead epithelium but where [illegible] dead epithelium the œdema [illegible] subside when much water wa[illegible] that excessive water drink[illegible] metabolism and the work of the heart The symptoms of uræmia were suggestive of a poison in the blood, but there was no evidence that it was derived from the food A woman took 5000 kilocalories of food a day for 55 days, during that time she retained 120 grammes of nitrogen but no uræmic symptoms developed Probably the uræmic poison was formed from the tissues of the body The physician could only aid the elimination of the poison by means of hot air baths and hot drinks to assist perspiration or by transfusion of saline fluid. Pilocarpine was apt to cause œdema of the lungs Chloroform relieved uræmic convulsions Egypt had an ideal winter climate for patients with renal disease, but it should be remembered that warm clothes were required after sundown and proper food for invalids might be difficult to obtain far up the Nile

Professor CARL VON NOORDEN (Frankfort, Germany), alluded to the paper which he read at the Manchester meeting of the British Medical Association regarding several points of treatment of chronic Bright's disease First, regarding the difference of white and red meats he was the first who showed by scientific investigation that the red meats were no more harmful than the white meats in chronic Bright's disease All the publications which had appeared since then agreed with his opinion, as did also Dr Hale White Secondly, regarding the supply of water in chronic Bright's disease, he had shown by clinic[illegible]tion and research on [illegible] (one and a half litres [illegible] of urea on the one hand, and on the other it spared the heart A third question studied by Professor von Noorden was the amount of muscular exercise advisable in chronic renal disease He did not consider it wise to keep the patient in bed, as many French and German physicians had done It was better to give cautiously a systematic muscular training, with special reference to the heart Albuminuria rose during the first few days or weeks of such treatment and then diminished again It was preferable not to undergo the training in muscular exercise at home, better results were obtained at hospitals and health resorts A fourth question was the treatment of the dangerous and frequent complication of obesity Care should be taken not to reduce obesity too rapidly in cases of chronic renal disease A healthy person might lose from four to six kilos in a month, when chronic renal disease was present four months should be allowed for the same loss of weight Professor von Noorden referred to the importance of not checking the diarrhœa in uræmia, and mentioned that he had found by experiment that the greatest amount of nitrogen excreted by the skin in one day was three grammes, and by the bowel eight grammes

Sir JOHN MOORE (Dublin) stated that deaths from [illegible] on in Dublin Chronic [illegible] than chronic interstitial [illegible] had become much less common since the city had had an abundant soft water supply from the Vartry river He regarded the lungs as an important path of elimination and therefore open air treatment was as important in chronic renal disease as in pulmonary tuberculosis Uræmic coma was often averted by giving 20 grains of benzoate of soda He had tried with unsatisfactory results the method of treatment lately recommended by Professor Renaut of Lyons, which consisted in administering macerated fresh pork kidneys

Professor JAMES TYSON (Pennsylvania) agreed with Professor von Noorden that red and white meats were equally suitable in chronic renal disease and that water in excess was dangerous. Morphine was in most cases unsuitable but it might be given without danger in uræmic convulsions occurring in a case of chronic parenchymatous but not in interstitial nephritis Methylene blue was eliminated in parenchymatous but not in interstitial nephritis and the same [illegible] He quoted a case of [illegible]g his belief that de[illegible] cure the disease

[illegible] (London) regarded water as of considerable use for flushing the kidneys, especially when taken apart from meals The progress of a case of chronic renal disease could not be judged by the amount of albumin; the specific gravity was much more important Mild repeated doses of mercury had more effect in reducing arterial tension than salines The worst symptoms of uræmia were dependent not upon poisons but upon arterial tension Uræmic convulsions were of circulatory origin He referred to a case of convulsions which in his view was due not to renal disease but to high arterial tension in which bleeding was followed by complete recovery and non recurrence The hot air bath required considerable discussion, for they might determine convulsions by weakening the heart

Professor ROBERT SAUNDBY (Birmingham) quoted several cases of great interest in illustration of the longevity of some cases suffering from renal disease One was a case of a young man who had been previously seen by the late Sir George Johnson and warned to avoid athletics, he, however, persevered in outdoor sports and was seen by Professor Saundby 20 years later when he had cardiac hypertrophy, hard radials, a considerable amount of albumin, and some tube casts in the urine Professor Saundby had seen cases of nephritis during pregnancy accompanied by albuminuric retinitis which had completely recovered excepting from the eye symptoms

Dr SAMUEL WEST (London), addressing himself in the first place to the question of diet, remarked that in acute nephritis it was usual to place the patient upon a milk diet, and rightly so, considering that it was mainly by the kidneys that effete nitrogenous products were eliminated; but during convalescence milk was not the best food for adults, their nutrition suffered, and the advantage of a change from milk to a more varied and liberal diet was a matter of daily experience. With granular kidney the case was somewhat different and these patients, in his experience, never throve upon a purely milk diet. The amount of albuminuria could never be taken as the guide to the diet required, excepting perhaps that where much albumin was present in the urine, as little albumin as possible should be given in the food. Turning to the use of drugs, digitalis was useful when the tension was low and antimony when it was high. In chronic parenchymatous nephritis the tension was almost always low and in this condition digitalis was the stock remedy because of its action on the heart as well as on the arteries. The normal tension in granular kidney was raised, but it might vary in either direction, the high tension being also either further raised or even becoming low, and treatment must be adopted accordingly. Antimony was not a good remedy in granular kidney for it produced much depression. Of the other drugs which reduced tension the most important were the nitrites and after them pilocarpine. Chronic uræmia consisted of the cachexia which developed in chronic renal disease and it was just such a general deterioration of health as the want of an internal secretion might produce; it was for this especially that renal extracts had been given. Acute uræmia, acute renal toxæmia, was a very different condition. It was due to some internally toxic substance circulating in the blood and a rational method of treatment would seem to be abstraction of blood associated or not with intravenous saline injection. Another method of more promise was the saturation of the blood with oxygen with the object of oxidising these venomous substances and thereby diminishing or removing their toxicity.

Dr. J. **FINLAYSON** (Glasgow) endorsed the remarks of previous speakers on the advisability of treating chronic renal affections on a totally different plan from that pursued in acute nephritis. Rest in bed and strict milk diet were not advisable in chronic cases.

Dr. J. **ROSE BRADFORD** (London) disagreed with the view that the amount of albumin lost was of no importance. As much albumin could be lost in a day as was contained in two pints of milk. He agreed, however, that the specific gravity was a better indication of the progress of the disease. A milk diet was advisable for chronic renal disease, but only in those cases which did not lose weight while taking it. Morphine was useful in certain cases, especially with dyspnœa, and it was inadvisable in cases with dropsy, but no definite rules could be laid down as to its use. He declared that there was no evidence to show that the kidney had any internal secretion. Venesection, followed by transfusion, was in some circumstances a valuable means of treating uræmia.

Dr. J. **BARR** (Liverpool) confirmed the remarks made by Professor Saundby as to the longevity of cases with chronic interstitial nephritis, and Dr. **DAVID NEWMAN** (Glasgow) described a method of venesection in nephritis.

SURGERY.

WEDNESDAY, JULY 27TH.

Introductory Remarks by the President.

Mr. H. P. **SYMONDS** presided and in opening the meeting made a few remarks on the subject proposed for discussion. He said that those who were only acquainted with modern surgery could not appreciate the condition of things before the introduction of antiseptic surgery. He himself had commenced the study of medicine in 1869 when, he might say, such a thing as primary union was never seen. He had also had the opportunity of seeing the result of wounds and operations in the Franco-Prussian war, when the mortality from amputations was exceedingly great and septic troubles of all kinds were the rule. All this had been changed by the methods of Lister. It was true that at first the technique was cumbersome and the details were many but there was one countervailing benefit; as the method was but little known the surgeon had to attend to all the details himself and thus were obtained the very excellent results which the new method gave at once. On one other point he wished to express an opinion; he thought that all surgical cases should, as far as possible, be treated in the open air; a method already employed in tuberculosis but applicable equally well to many other conditions. The most recent addition to the prevention of sepsis after operations was originally suggested by Mikulicz who advised the hypodermic injection of nuclein and other substances to set up a hyperleucocytosis, by which the resistance of the tissues was greatly increased. That surgeon was best fitted for the practice of surgery who had had a bacteriological training.

A discussion on *Asepsis and Antisepsis* was opened by Mr. F. F. **BURGHARD**, in the unavoidable absence of Mr. W. Watson Cheyne. He commenced by saying that all surgeons were agreed that a wound made by a surgeon into a non-septic part should be free from germs, that is, "aseptic," but the method by which this aseptic condition should be attained was the cause of much discussion but this difference of opinion could not apply to cases which were already septic when the surgeon operated. He continued: The standard by which the results of operations are judged is now very much higher than it was for some years after the introduction of the antiseptic method of Lister. Formerly a surgeon was satisfied with his results even though a little pus formed in a fair proportion of his cases but now even the slightest formation of pus is sufficient to condemn a wound as septic. Others say there should be no redness or swelling around a wound. Others are even more particular, for they insist on a wound and the surrounding parts proving sterile when examined by bacteriological culture tests. There are three channels by which infection can reach a wound. In the first place germs can enter a wound by the instruments employed. In the second place they can come from the skin of the patient or the hands of the surgeon or of his assistants. As a rule, true pathogenic bacteria do not reside in healthy skin; there are numerous germs present but they are usually harmless; still the skin is a fertile source of infection. The third channel by which micro-organisms can reach a wound is the air. Those who advocate what they call a pure "aseptic" surgery are inclined to minimise the dangers of infection by the air, but a very little experimentation with Petrie dishes exposed in the neighbourhood of an operation will show that many micro-organisms will settle during the time an operation is proceeding, it is true that most of these are non-pathogenic, but there is always the risk that pathogenic organisms may thus gain access to the wound and this danger should be guarded against. There are two methods by which micro-organisms can be destroyed—heat and antiseptics. Heat can be employed in three ways: first, by hot air, but this method needs expensive and troublesome apparatus and is therefore little used. Secondly, by boiling in water; this method is much employed but for thorough sterilisation boiling for half an hour is required and, though this is possible for instruments put out for an operation, it is not possible if an instrument is suddenly required in the middle of an operation. The third method is by superheated steam, but in Mr. Burghard's opinion this is suitable only for trays and basins. With regard to the skin, heat cannot be employed and therefore recourse must be had to the use of chemicals, and even those who sterilise the instruments and dressings by means of heat employ antiseptics for the skin. With regard to the tissues in a wound no one favours the employment of strong antiseptics, but the use of dilute antiseptics in a wound can do no harm. He employs heat to sterilise instruments as a rule, but when an instrument is required during an operation it is dipped for five minutes in liquefied carbolic acid and then it is placed like the other instruments in a 1 in 20 carbolic acid solution. The paper ended with various details as to the preparation of instruments, the disinfection of the skin, the use of sponges, the preparation of catgut, and towels.

Mr. C. A. **LEEDHAM-GREEN** (Birmingham), in continuation of the discussion, read a paper on the Sterilisation of the Hands, in which he described some experiments made to determine the relative value of various methods employed by which he had arrived at the following conclusions. That even after the most prolonged and energetic washing of the hands in soap and hot water it is not possible materially to diminish the number of microbes on them and that the form of soap employed causes no real difference; that, however prolonged the washing is, nothing is really gained; neither is there much value in using soft soap, turpentine, benzol, xylol, or aqueous solutions of carbolic acid, lysol, perchloride, or biniodide of mercury. Kelly's method of applying a saturated solution of permanganate of potash followed by a solution of oxalic acid gives wholly inadequate results Soaps containing biniodide of mercury or lysol are practically valueless for cleansing the hands Alcohol far surpasses all other agents for cleansing the hands but it should be employed for four or five minutes especially when in a 70 per cent solution It is essential that the hands should be smooth The best results were obtained by the following methods (*a*) the hands were first scrubbed for five minutes with soap and very hot water (about 50° C), (*b*) then rubbed with methylated spirit for three minutes , (*c*) then scrubbed for a minute or two with 70 per cent sublimate alcohol (1 in 1000), and (*d*) finally rubbed until dry and polished with a sterile cloth As no method of cleansing the hands guarantees sterility it is desirable that impermeable gloves should be worn when the nature of the operation will permit, whether the wound be aseptic or not

Mr H ,
believed t ,
ing with
of opinio
which infection was derived Some of the sources of danger might easily be provided against for heat was an absolutely efficient steriliser when it could be used , when it could not be used the less reliable method of chemical disinfection had to be adopted That chemical disinfection was unreliable could be shown by the fact that much commercial "sterilised" catgut will infect culture tubes Complete disinfection of the skin of the operator and of the patient was almost impossible, for even if the surface of the skin at the commencement of the operation was sterile, yet during the course of the operation micro organisms from the deeper layers of the epidermis worked to the surface Air infection could not be prevented, but one of the most important points in preventing infection through the air was to take care that the air was as still as possible, and that no dusting or sweeping was done before the operation No wound was absolutely aseptic for if the surface of a wound was tested by cultures immediately before it was closed infection would always be found to be present The tissues destroyed micro organisms to a certain extent and it was better to let them exercise this power than to employ strong antiseptics in the wound and thus reduce greatly the resistance of the tissues Finally, it was important to do as little damage as possible to the edges of the wound and to keep it as dry as possible

Mr H J **STILES** (Edinburgh) considered that the treatment of wounds depended not so much on the method *employed as on the care with which it was carried out* The preparation of th verdone He
prepared the skin then applied
a dry dressing, a immediately
before the operation As to the dressings for the wound he often used none but merely put on some iodoform from cumol He had employed this in 100 cases of hernia in children with excellent results When a wound was not to be disturbed for two or three weeks he thought it well to use an antiseptic dressing

Mr K W **MONSARRAT** (Liverpool) thought that a surgeon should always test his methods bacteriologically The method used for the patient's skin had to vary with the region operated on but an alcoholic solution of the biniodide was very useful He considered that gloves were essential for only by the use of gloves could a surgeon guarantee that his hand did not infect the wound After the operation it was well to wash out the wound with sterilised water

Mr G G **HAMILTON** (Liverpool) gave a list of a year's work Out of 154 operation cases only six did not heal by first intention He thought it desirable to do without assistants so far as possible

Mr J P **BUSH** (Bristol) said that he had given up Kelly's method of hand disinfection and had gone back to immersion of the hands in a solution of carbolic acid or perchloride of mercury Dressings were of very little importance

Professor **RODMAN** (Philadelphia) said that by no method was it possible to sterilise the hands except perhaps by the use of chlorinated lime and water followed by carbonate of sodium, but this was too severe for everyone except those with very thick skins It was best for the surgeon to wear rubber gloves Washing for five to ten minutes was of great value in cleansing the skin

Mr C W **CATHCART** (Edinburgh) thought it of great importance for those engaged in teaching to practise such a *method as could be followed out by their students His* house surgeon who assisted him wore gloves, but rarely put his hands into the wound

Sir **WILLIAM MACEWEN** (Glasgow) said that he practised aseptic surgery, but the skin was cleansed with soap and carbolic acid solution on two or three occasions The surgeon's hands were periodically tested bacteriologically, and he required that all his assistants should steep their
lution of carbolic acid

Mr H **DAVIES** (Greenwich), Mr J **WARD COUSINS** (Portsmouth) Mr A B **MITCHELL** (Belfast), Mr W A **MEREDITH** (London) Dr J **LAURIE**, and Dr W T **BROOK FOX** (Blyth)

Dr G H **EDINGTON** (Glasgow) read a paper on Median Cysts of the Neck It was based on several cases observed by him All these cysts were developed from the thyro glossal tract as first described by His He gave details of some of his cases and pointed out that these cysts might appear superficially to the deep fascia

PATHOLOGY

WEDNESDAY, JULY 27TH

The section met in the Pathological Department, University Museum *The President, Dr* **JAMES RITCHIE** (reader in pathology, University of Oxford), whose address was practically the opening contribution to the discussion on Immunity, briefly reviewed the present day theories on the subject, differentiating established facts, laying stress on the complexity of the problems needing elucidation, and indicating the trend of the most recent work

Dr W **BULLOCH** (London) followed with a paper on the Cellular Aspects of Immunity

Dr **GEORGES DREYER** (Copenhagen) and Dr A J **JEX-BLAKE** (Oxford) detailed their experiments on Agglutinins in Relation to Immunity, and Dr **MADSEN** (Copenhagen), in his paper on the Neutralisation of Lysins, pointed out the applications of the methods of physical chemistry to the elucidation of these biological reactions

Dr C J **MARTIN** (Lister Institute) and Dr **NOGOUCHI** dealt with Snake Venom in Relation to Immunity, the former discussing the broad general principles brought out by the study of this branch of the subject , the latter dealing with the specific results obtained by the therapeutic use of various antivenins

Dr M A **RUFFER** (Alexandria), in a paper on Hæmolytic and Hæmosozic Sera dealt with the preparation and *characters of these substances, after which the section* adjourned

On resuming, in the course of a discussion on Immunity, Professor **MUIR** (Glasgow) described his experiments on the Nature of Hæmolysis and was followed by Dr A E **WRIGHT** (London) on Opsinines and their Relation to Immunity in which he explained the nature and action of these substances

PSYCHOLOGICAL MEDICINE

WEDNESDAY, JULY 27TH

The meeting of the section was held in the Morphology Lecture Room of the University

The Presidential Address was delivered by Dr **CHARLES A MERCIER**, the subject of the address being Criminal Responsibility and Degeneracy A lengthy discussion followed the reading of this paper and among those who took part in it were Mr A **DOUGLAS COWBURN**, Dr T **CLAYE SHAW**, Dr G H **SAVAGE**, Dr **DAVID YELLOWLEES** Dr G F **BLANDFORD** Dr T B **HYSLOP** Mr **CONOLLY NORMAN** Dr **ROBERT JONES**, Dr **ERNEST W WHITE** and Dr G L **SHUTTLEWORTH** after which the **PRESIDENT** replied *Letters contributory to the subject matter of the* discussion were sent by Sir **HERBERT STEPHEN** and Mr **HAVELOCK ELLIS** which were, in the absence of the writers, read by the **SECRETARY**

A lantern and microscopical demonstration on degenerative lesions of the posterior columns of the cord in general paralysis with remarks on the point of origin of tabes dorsalis was given by Dr **DAVID ORR** and Dr R G **ROWS** The view was maintained that the local vulnerability of certain points in the posterior root fibres of the spinal cord was due to anatomical conditions of the nerve sheaths as demonstrated on the screen An explanation of the patho*genesis of tabes was then given, based on the facts of the* vulnerability referred to This concluded the proceedings of the first day

PHYSIOLOGY.

Wednesday, July 27th.

This section met in the Physiological Laboratory under the chairmanship of Professor Francis Gotch. Dr. E. I. Spriggs gave an account of the work done by Dr. A. P. Beddard and by himself in connexion with the Metabolism of Diabetes, Professor W. H. Thompson and Dr. Ramsden joining in the discussion which followed.

Dr. W. L. Braddon described and exhibited Structures in Red Blood Corpuscles Stained by Alkaline Solutions of Methylene Blue when the blood film had not been previously dried.

Dr. R. Kennedy communicated his views and further observations on the Histological Changes occurring in Ununited Divided Nerves, his remarks giving rise to an interesting discussion by Professor Gotch, Professor Wesley Mills, Dr. W. B. Warrington, and Professor Thompson.

Dr. Warrington and Dr. F. Griffith gave an account of their work upon the Varieties of the Cells of the Spinal Ganglia and their Relationship to Axons of Different Distribution.

Dr. H. M. Vernon read a paper on the Protective Value of Proteids and their Decomposition Products on Trypsin exposed to Dilute Alkaline Solutions.

ANATOMY.

Wednesday, July 27th.

This Section met in the Lecture Theatre of the Department of Human Anatomy, Professor A. Thomson, the President, being in the chair. Dr. C. J. Patten communicated a paper on a New Method of Mounting Anatomical Preparations for Museum Purposes. Dr. G. H. Bryce read a paper on the Origin of Embryonic Leucocytes and Professor Robinson and Professor F. Keibel joined in the discussion. The rest of the sitting was devoted to a discussion on Giants and Dwarfs which, after being opened by Professor D. J. Cunningham, was continued by Professor B. C. A. Windle, Mr. Hastings Gilford, Professor A. Dixon, Dr. Peter Thompson, Dr. G. A. Gibson, Dr. Gladstone, Dr. Patten, Dr. Gustav Mann, and Professor Symington.

OPHTHALMOLOGY.

Wednesday, July 27th.

The sections met in Keble College under the presidency of Mr. R. W. Doyne (Oxford), who offered a special welcome to the many visitors from America, France, and Germany who proposed to join in the work of the section.

A discussion on Retro-bulbar Neuritis was opened by Mr. R. Marcus Gunn (London), who was followed by Mr. G. A. Berry (Edinburgh), Professor Uhthoff (Breslau), Mr. C. Higgens (London), Mr. F. Richardson Cross (Bristol), Professor Oliver (Philadelphia), Dr. A. H. Griffith (Manchester), Mr. E. Nettleship (London), and Dr. Miller. Mr. Gunn replied.

An interesting paper was read by Professor Poulton, F.R.S., on Conclusions as to Vision of Birds based upon a Consideration of Mimetic Colour and Pattern in Insects. A paper on the Maturation and Extraction of Senile Cataract was read by Mr. M. M. McHardy (London) and discussed by Mr. Higgens, Dr. Griffiths, Dr. J. Tatham Thompson (Cardiff), Dr. K. A. Grossmann (Liverpool), and Dr. F. A. Thomas (Swansea).

Dr. Grossmann read a paper on Cases of Astigmatism with Variable Axes, which was discussed by Mr. Berry and Professor Bull (Paris), and after a reply from Dr. Grossmann the section adjourned.

On resuming several demonstrations of specimens, drawings, and instruments were given in the special museum of the society.

DERMATOLOGY.

Wednesday, July 27th.

This section was presided over by Dr. T. Colcott Fox.

Dr. A. Douglas Heath read a paper on Acne Keloid and demonstrated the case. Dr. Fox, Dr. H. A. G. Brooke, Dr. Gilchrist (Baltimore), and Dr. J. M. H. MacLeod joined in the discussion.

Dr. W. T. Freeman showed a case of Leucokeratosis Buccalis and a case of Congenital Pemphigus, and Dr. H. Radcliffe Crocker, Dr. Gilchrist, Mr. G. Pernet, and Dr. F. Leslie Phillips spoke in the subsequent discussion.

Mr. Malcolm Morris opened a discussion on Pruritis Ani, and Dr. Fox, Dr. Crocker, Miss E. L. Walker Dunbar, Dr. Freeman, Dr. M. B. Hartzell, Dr. Norman Walker, Mr. Pernet, Dr. Harrison, and Dr. Gilchrist spoke.

Dr. Hartzell read a paper on Benign Cystic Epithelioma, and Dr. Brooke and Dr. Gilchrist discussed the paper.

Mr. Pernet read a paper on Bacillus Pyocyaneus and Pemphigus Vegetans.

LARYNGOLOGY AND OTOLOGY.

Wednesday, July 27th.

This section met in the class room in the museum under the presidency of Mr. J. Charters Symonds (London), who, after welcoming the visitors, gave a brief address.

A discussion on

The Treatment of Non-Suppurative Disease of the Middle Ear

was opened by Dr. Urban Pritchard (London) and Dr. Thomas Barr (Glasgow.)

The discussion was continued by Dr. Adolph Bronner (Bradford), Dr. Marcel Natier (Paris), Dr. J. Walker Downie (Glasgow), Mr. F. Marsh (Birmingham), Dr. William Milligan (Manchester), Dr. L. H. Pegler (London), Dr. B. H. Scanes Spicer (London), Dr. H. Smurthwaite (Newcastle), Mr. E. Waggett (London), Dr. Cecil E. Shaw (Belfast), Mr. C. H. Fagge (London), Mr. W. Hill (London), Dr. A. J. Brady (Sydney, N.S.W.), Dr. J. E. Neucomb (New York), and Dr. W. Jobson Horne (London).—The President summed up the discussion and the openers replied.

The translation of a paper contributed by Professor Ouodi of Budapest on the Disturbances of Vision and Development of Blindness of Nasal Origin induced by Diseases of the Posterior Accessory Sinuses was read by Dr. Horne.

TROPICAL DISEASES.

Wednesday, July 27th.

The President, Dr. Alexander Crombie delivered an introductory address entitled

"*The Fallacy of Finality*,"

in which he pointed out that a large proportion of the febrile attacks of hot climates must still be included in the term "febricula" and "simple continued fevers," and that the evidence that they were medical was inadmissible.

Colonel David Bruce, R.A.M.C., opened a discussion on "Trypanosomiasis" in which he contended that the trypanosoma Gambiense was undoubtedly the cause of trypanosomal fever and of sleeping sickness, and that the glossina palpalis was the carrier of the disease. The discussion was continued by Dr. D. N. Nabarro, Dr. C. Christy, Sir Patrick Manson, and Dr. Louis Sambon.

A paper on Trypanosomiasis and its Relations to Congo Sleeping Sickness (second progress report of the Liverpool School of Tropical Medicine Expedition to the Congo in 1903) was communicated by Dr. Christy, Dr. J. E. Dutton, and Dr. J. Todd.

A paper entitled "A New Trematode of Man" (Amphistoneum Watsoni) was communicated by Mr. H. F. Conyngham, demonstrator at the London School of Tropical Medicine.

"The Treatment of Snake Bites" was the title of a paper sent by Captain Leonard Rogers, I.M.S., acting professor of pathology, Medical College, Calcutta.

Mr. Ernest E. Austen, Zoological Department, British Museum, communicated Supplementary Notes on the Tsetse Flies (Genus Glossina, Wiedemann).

Papers on Floor Maggots met with in Houses on the Congo and on Cerebro-spinal Fluid in Sleeping Sickness (Trypanosomiasis) were communicated by Dr. Christy.

Dr. E. Anderson of Paris and Mr. T. J. Tonkin, joined in the discussion.

NAVY, ARMY, AND AMBULANCE.

Wednesday, July 27th.

Surgeon-General A. Frederick Bradshaw (the President), in a short introductory address, indicated the direction of the labours of the section.

Major E. C. Freeman, R.A.M.C., then read a paper on the Sanitation of Camps and this was followed by a communication on Sanitation in Volunteer Camps, contributed by Surgeon-Lieutenant-Colonel P. B. GILES, A.M.R. A paper by Staff-Surgeon J. FALCONER HALL, R.N., on the Present Dietary on Board a Man-of-War, was read and in the debate which followed the question of sanitation in connexion with the papers contributed was discussed.

A report by Major J. F. DONEGAN, R.A.M.C., on the Duties of a Medical Officer with a Regimental Unit in the Field was read; also a paper by Lieutenant-Colonel A. M. DAVIES, R.A.M.C., on the Sterilisation of Infective Discharges and Utensils on Field Service.

A paper on the Recruiting Problem, by Surgeon-Major W. C. BEEVOR, followed, and was fully discussed by Deputy-Inspector-General T. J. PRESTON, R.N., Surgeon-Major G. A. HUTTON, Fleet-Surgeon J. LLOYD THOMAS, R.N., and Major R. C. LEVER, R.A.M.C.

DENTAL SURGERY.

WEDNESDAY, JULY 27TH.

The meeting of this section was held in the Pharmacological Department under the presidency of Mr. E. A. BEVERS. The PRESIDENT read a short address. A discussion took place on Oral Sepsis, the subject being introduced by the following papers: Oral Sepsis as Related to General Surgery, by Mr. RICKMAN J. GODLEE; Oral Sepsis in its Relation to General Medicine, by Dr. W. HUNTER; the Pathology of Oral Sepsis, by Mr. KENNETH W. GOADBY. The following took part in the discussion: Dr. DALTON, Dr. STCLAIR THOMPSON, Dr. H. TILLEY, Professor J. ARKÖRY (Budapest), Mr. NORMAN BENNETT, Mr. J. G. TURNER, Mr. HERN, and Mr. E. LLOYD-WILLIAMS.

THE ANNUAL EXHIBITION.

OXFORD has provided excellent facilities for the exhibition of foods, drugs, and appliances of interest to the medical profession. The beautiful university city was sure to draw a large attendance and this fact was not lost sight of by intending exhibitors. As a result the exhibition was on a larger scale than in previous years and the number of visitors who attended must have been gratifying to all concerned. The accommodation placed at the disposal of the exhibitors was ample and every opportunity was offered for making the display attractive in the spacious and beautiful rooms situated on the first floor of the Examination Schools in the High-street. In the same picturesque building were the reception-room and the room in which the general meetings were held, so that the fact of an exhibition taking place could hardly escape the visitor, even though he were bent merely upon the discussion of the affairs of the Association or interested mainly in the social side of the meeting.

In regard to the exhibits, there was a noticeable falling off in one class while there was a decided increase in another. The sections more fully illustrated than before perhaps were those which we have hitherto included under the headings of "surgical instruments" and "sanitary and hospital appliances." Special foods were represented on much the same scale as in previous years but drugs, synthetic remedies and new methods of administration were not so prominent a feature. There were, however, many excellent displays typifying pharmaceutical elegance and skill. Electro-therapeutic apparatus attracted a good deal of interest and there was also a fair representation of scientific apparatus. Whilst adhering mainly to the classification adopted in former years we may depart from it by placing the sections in a slightly different order, giving those precedence which appeared to be more in evidence than has hitherto been the case. We propose therefore to deal with the sections in the following order. (1) Drugs; (2) Surgical Instruments and Appliances; (3) Sanitary Appliances, Disinfectants, &c.; (4) Foods and Food Products; (5) Mineral Waters, Beverages, &c.; (6) Publications; and (7) Miscellaneous.

I.—DRUGS.

Considerable attention has been paid to the preparation of suprarenal extracts, almost every manufacturing pharmaceutical chemist exhibiting special specimens of this powerful hæmostatic. In particular, Messrs. Parke, Davis, and Co., of 111, Queen Victoria-street, London, E.C., showed specimens of the hæmostatic principle in the form of adrenalin chloride, one part of which in 10,000 parts of water is stated to blanch the conjunctiva in from 30 to 60 seconds. The difficulty of making aqueous solutions has been overcome by the use of the chloride. A recent application of adrenalin chloride applied in the form of spray is its use in hay fever. We have already mentioned in our analytical columns acetozone, or benzoyl-acetyl-peroxide, which proves to be a powerful germicide, equal in this respect to 1 per 1000 mercuric chloride solution, whilst it may be administered internally without harm. Amongst other products on this stall we noticed digitalin, which is described as an aseptic, non-alcoholic, non-irritating, permanent solution of digitalis standardised physiologically. The exhibit also included a series of lantern-slides illustrating the preparation of serum, the physiological testing of drugs, and a series of charts illustrating the effect of adrenalin and digitalin on heart and blood pressure. The Bayer Company, Limited, of 19, St. Dunstan's-hill, London, E.C., showed some of their fine specimens of pharmaceutical products. Amongst these may be mentioned aristol, an iodine thymol derivative, described as a "cicatrisant" for burns, ulcers, and purulent discharges; citarin which has been used in the treatment of gout and as an analgesic in cases of rheumatism; helmitol, a new urinary antiseptic liberating formaldehyde both in alkaline and acid urines; mesotan, a derivative of salicylic acid and a substitute for winter green oil but without, it is said, the disagreeable properties of the latter; and lastly, veronal or malonyl urea, a new hypnotic which is said to induce sleep without harmful effects. One of the best examples of pharmaceutical display was that of Messrs. Brady and Martin, Limited, of Newcastle-upon-Tyne. Their preparations included ergotinol, a standard preparation of ergot which has been used with consistent results in gynæcological practice; capsules of ammoniated quinine, Easton's syrup, and several excellent liquors. Messrs. A. and M. Zimmerman of 3, Lloyd's-avenue, London, E.C., exhibited some interesting synthetics, amongst which may be mentioned exodin (Schering), a tasteless and odourless aperient causing no disturbance to the stomach; urotropine, a urinary antiseptic; beta-eucaine, which is chemically identical with cocaine but possessing advantages compared with that alkaloid in anæsthetic practice. This exhibit included sublamin, a powerful bactericide useful in particular for disinfecting the skin and mucous membrane. There were also other preparations illustrating "Schering's modern therapeutics." The stall of Mr. Frank A. Rogers of 327, Oxford-street, London, W., was chiefly occupied by a very complete set of medical sprays and atomisers simple in design and effective. The exhibit included also some pharmaceutical preparations and hypodermules of suprarenal gland solution. The Ferroleum Company, Limited, of 86, Clerkenwell-road, London, E.C., exhibited their specialty ferroleum, which is based on an excellent formula, including cod-liver oil, phosphate of iron, phosphorus, and glycerine. The point about the preparation is that the ingredients are completely emulsified. Purgen was the chief exhibit of Messrs. H. and T. Kirby and Co., Limited, of 14, Newman-street, London, W. Purgen is described as a non-irritating but effective aperient. It is said to have a constitution allied to the purgative principle of well-known vegetable extracts. The exhibit included some useful compressed tablets of drugs. Messrs. Andrus and Andrus of 46, Holborn Viaduct, London, E.C., drew the attention of the visitors to "hemaboloids" described as "a rational blood enricher and tissue reconstructive." Its claims as a real and effectual hematinic are based upon the fact that it contains iron as it exists in organic combination in vegetable food stuffs. It is further prepared with bone-marrow extract, beef peptone, and nuclein. Clinical observations are given which record the increase in the percentage of hæmoglobin of the blood after the administration of *hæmoboloids. Beside this preparation* were specimens of formolyptol, a pleasant, non-irritating, and non-poisonous bactericide. We have already pointed out the advantages of "antiphlogistine" which is in reality a scientific cataplasm in [illegible] in an affected or disc [illegible] soothing whilst antiseptic [illegible] results in inflammatory [illegible] shown by the Denver Ch [illegible] 110, Cheapside, London, E.C. [illegible] parations for which originality may be claimed were artistically displayed on the stall of Messrs. C. J. Hewlett and Son, of 35 to 42, Charlotte-street, London, E.C. Amongst *absentiâ*); and John Campbell Young, *B.Sc.*, Australia, M.B., C.M., 1884 (*in absentiâ*).

* Commended for their theses.
† Highly commended for their theses.
‡ Awarded gold medal for their theses.

Bachelor of Medicine and Master in Surgery.—Hugh Craigie Gibson, Scotland; and George Munro, England.

Bachelor of Medicine and Bachelor of Surgery.—Russell Gerald William Adams, New Zealand; David Irving Anderson, England; William Ward Anderson, England; James William Herbert Babington, Ireland; §Robert Balfour Barnetson, Scotland; William Purvis Beattie, Scotland; Douglas Bell, England; Lewis Hay Irving Bell, Scotland; James Bentley, Ireland; Alexander Robert Berrie, India; John Marthinus Beyers, Cape Colony; Arnold Samuel Longbotham Biggart, England; Dudley William Boswell, England; Frederick Thompson Bowerbank, England; §David Brown, Scotland; William Sanders Murdoch Brown, Scotland; §Hugh Clive Buckley, India; Vincent Theodore Carruthers, England; Mildred Margaret Lindsay Cathels, Scotland; §Robert Alexander Chambers, Ireland; Duncan Macdonald Cochrane Church, Scotland; George Stewart Clark, M.A., B.Sc., Scotland; Alexander Glover Coullie, Scotland; Thomas Edmund Coulson, England; George Cunningham, M.A., Scotland; John Michael Dewar, Scotland; Robert Donaldson, M.A., Scotland; §Arthur Mitchell Dryden, Scotland; Thomas Henry Easton, Scotland; Charles Gordon Edmonston, Scotland; Edward John Elliot, Scotland; Nicolai Christian Fischer, Scotland; §Jules Michael Ralph Flament, Trinidad; William Henry Forsyth, England; §Louis Fourié, Cape Colony; Alastair Norman Fraser, Scotland; ‖William James Fraser, Scotland; Frederick Henry Gibson, [illegible] Glass, M.A., Scotland; Alfred Marshall [illegible] Vivian Goldstein, England; Jean Pa[illegible], James Methuen Graham, Scotland; William Wells Greer, Australia; Evan John Griffiths, Wales; Thomas Mansfield Guthrie, Scotland; Philip Anthony Harry, Jamaica; ‖Ephraim Henderson, M.A., Scotland; Alexander Wilson Hogg, New Zealand; George Staunton Husband, Jamaica; Knollys Ulric Alexander Inniss, Trinidad; John Jardine, Scotland; Samuel Alexander Johnston, Ireland; John Kirk, Scotland; George Francis Stirling Landon, England; Samuel Walter Sydney Leary, Ireland; Arthur James Lewis, England; ‖James Lochhead, M.A., B.Sc., Scotland; Charles Damien Lochrane, Scotland; James Blacklay Lockerbie, Scotland; Isabella Logie, Scotland; Archibald Duncan McCallum, England; Hugh McCalman, M.A., Scotland; William McConaghy, Ireland; ‖John Pool McGowan, M.A., Scotland; §Hugh Ross Macintyre, Scotland; Norman Douglas Mackay, B.Sc., Scotland; Robert John Mackessack, M.A., Scotland; Amy Marion Mackintosh, Scotland; Elspeth Mary Macmillan, Scotland; Alexander MacRea, M.A., Scotland; Alfred Malseed, Ireland; Murat Marcus Mamourian, Smyrna; David Pieter Marais, South Africa; Aimée Eveline Mills, M.A., B.Sc., New Zealand; Lindsay Stephen Milne, Scotland; Gerald Irving Moriarty, Ireland; Thomas Bernard Mouat, Scotland; William Maxwell Muney, England; Donald Sutherland Murray, Scotland; Archibald Oliver, Scotland; Charles Duncan O'Neal, Barbados; Armand Pampellonne, Trinidad; William John Patterson, Ireland; William Patton, Ireland; Bernand Pickering, England; Florence Margaret Sarah Price, Wales; Labbhu Ram, India; Charles Reece, New Zealand; Alfred Ernest Carey Rees, B.A., England; Hugh Smith Reid, Scotland; Charles Henry George Ritter, Cape Colony; Margaret Helen Robertson, Scotland; William James Dunlop Robertson, Scotland; Joseph Robinson, B.Sc., England; Sheila Margaret Ross, Scotland; Charles Sydney Ryles, England; John Saffley, Scotland; John Glendinning Bryden Shand, Scotland; John Ingram Shepherd, M.A., Scotland; Frederick Ritchie Sinton, Scotland; Charles Johnston Smith, Scotland; George M'Call Smith, Scotland; William Arthur Wilson Smith, Scotland; Patrick Steele, Scotland; Francis Hugh Stewart, M.A., B.Sc., Scotland; Hugh Angus Stewart, Scotland; §Arthur Charles Strain, Scotland; Kenneth Andrew Moody Stuart, Scotland; Stuart Hopcraft Stanley Taylor, B.A., England; Herbert Marshall Thompson, England; Robert Stanley Enever Todd, M.A., B.Sc., Scotland; George Herbert Ussher, New Zealand; Robert Milne Walker, Scotland; Robert William Lessel Wallace, Scotland; Robert Honey Watt, Scotland; John Henry Douglas Webster, Scotland; David Percival Dalbreck Wilkie, Scotland; Friedrich Adolf Wille, Cape Colony; William Bruce Wishart, Scotland; Alfred Chad Turner Woodward, England; Cyril Haworth Wright, B.A., England; Thomas Wright, Ireland; and Margaret Campbell Wylde Young, M.A., Scotland.

UNIVERSITY OF ABERDEEN.—The following degrees and diploma have been conferred:—

Degree of Doctor of Medicine (M.D.).—Middleton Connon, M.B., C.M., *Montrose (under old regulations); James Cran, M.B., C.M.*, Belize, British Honduras (under old regulations); Ernest King Gawn, M.B., C.M., London (under old regulations); Henry Gibbons, M.B., C.M., Market Harborough (under old regulations); Peter Harper, M.A., M.B., C.M., London (under old regulations); *David Albert Hutcheson, M.B., Ch.B., Aberdeen; †Arthur Hugh Lister, B.A., M.B., C.M., Aberdeen (under old regulations); ‡Hugh MacLean, M.B., Ch.B., Aberdeen; John Smith Purdy, M.B., C.M., Morpeth [illegible] *Arthur Westerman, M.B., Ch.B., London; [illegible] on, M.B., C.M., Aberdeen.

* [illegible] r thesis. † Honours for thesis.
‡ Highest honours for thesis.

Degree of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.).—§Cyril Moore Smith, Cheshunt, Herts (with second-class *honours*); *Catherine Emslie Anderson* and John Anderson, Aberdeen; Wm. Robert Catto, Aberdeenshire; William Gillespie Bryson Gunn, Cullen, Banffshire; Alexander Hendry, Ellon, Aberdeenshire; Thomas Christie Innes, Skene, Aberdeenshire; Henry Williams Jeans, Portsmouth; John Jenkins, M.A., Burghead; Frederick Leonard Keith, Helen M'Glashan, and Roderick Mackay, M.A., Aberdeen; James Reid, M.A., Dublin; Michael Balfour Hutchison Ritchie, Inverurie; Fife Slater, Hopeman, Morayshire; James Hutcheon Thomson, Turriff; and Robert James Barron Wright, Forgue by Huntly.

§ Passed final examination "with distinction."

Diploma in Public Health.—Hugh Johnston, M.B., Ch.B. Aberd., Auchnagatt; and William Mackie, M.A., M.B., C.M. Aberd., Elgin.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGE OF PHYSICIANS AND ROYAL COLLEGE OF SURGEONS.—The following candidates have passed the third examination as undernoted:—

Passed in all Subjects.—T. A. Burke, M. Cohen, E. G. Condon, P. F. Foran, W. Glennon, C. W. Greene, W. P. Kelly, T. H. Massey, M. O'Connor, J. R. Tobin, and C. H. Wilson.

Completed Examination.—R. Calnan, C. J. R. Clarke, S. C. Clarke, T. W. Conway, J. Corboy, J. B. Dwyer, T. J. Golding, P. E. Hayden, R. F. Hayes, H. Hosty, A. E. S. Irvine, L. F. Kelly, M. J. C. Kennedy, F. G. McCaughey, T. J. Madden, R. V. Murphy, J. O'Donnell, W. D. Sammon, P. D. Sullivan, and W. G. Wright.

First Examination in all Subjects.—P. J. Timoney.

THE CENTRAL MIDWIVES BOARD.—The members of the Central Midwives Board met on July 21st at 6, Suffolk-street, London, S.W., Dr. F. H. Champneys being in the chair. A letter was read from the Registrar-General as to death certificates of midwives. It appears that it is the duty of the various local authorities mentioned in the Midwives Act to report to the Central Midwives Board the deaths of midwives. It was decided that Mr. J. Heywood Johnstone, M.P., one of the members of the Board, should be asked to bring the matter before the Association of County Councils. A letter from the town clerk of Brighton inclosing a report by the medical officer of health of Brighton on the working of the Midwives Act was then read and the Board decided to ask the town clerk of Brighton to forward a report on the matter for its consideration. The following is the scheme of examinations which will come up for final consideration in the autumn:—

Examiners.—1. A list of examiners, both for London and the provinces, shall be prepared by the Central Midwives Board from those who are willing to serve and act when required by the Board. This list shall be subject to annual revision by the Board. Before such a list is formed application for the post of examiner shall be invited by advertisement [illegible] shall be partly oral and practical and [illegible] conducted by not fewer than two examiners [illegible] mine his own pupils. 4. The first examination shall be held in May, 1905. 5. Thereafter the examination shall be held four times a year, or oftener if necessary, in London and the provinces simultaneously on the same papers. The Board reserves to itself the right to appoint one or more qualified medical practitioners as visitors of the examinations, both London and provincial, when it appears desirable. 6. The first provincial centres shall be: (*a*) Bristol; (*b*) Manchester; [illegible] Tyne. 7. A paper of directions to examiners [illegible] issued to each examiner on his appointment. [illegible] an examiner shall be at the rate of 7*s*. for each candidate examined.

London examiners.—1. The examiners, both London and provincial, shall be invited to meet at the offices of the Central Midwives Board as often as may be necessary. 2. The ar[illegible] shall be made by the secretary of t[illegible] such extra assistance as may be necess[illegible] examiners shall be: (*a*) To consider [illegible] by provincial examiners. (*b*) To set all the papers of examination questions both for London and the provinces. Two of the examiners, with the assistance of one of the medical members of the Board to be appointed for the purpose, shall undertake this duty in rotation. The remuneration of the examiners shall be two guineas each. (*c*) To conduct the examination, written and oral, of all candidates presenting themselves for examination in London. (*d*) To report to the Central Midwives Board the result of each examination held in London.

Provincial examiners.—1. The examiners appointed by the Central Midwives Board to conduct the Board's examinations in a provincial centre shall assist the secretary of the Board in making the necessary arrangements for the examinations. 2. One of the examiners shall be responsible for reporting the result of each examination to the Central Midwives Board.

Directions to examiners.—1. The paper shall consist of not fewer than six questions and the time allowed for answering shall be three hours. 2. Notes should be taken either by the examiner himself or by a colleague of the subjects upon which the candidate is questioned in the oral examination. 3. 15 minutes should be considered an average period for the oral examination of each candidate. 4. Examiners should avoid questioning candidates as to where and by whom they were trained so as to avoid any suspicion of bias.

THE LATE DR. GEORGE CHARLES WIGAN OF PORTISHEAD.—A beautiful stained-glass window of three lights in memory of the late Dr. G. C. Wigan and Mrs. Wigan has been placed in Portishead (Somerset) parish church and was dedicated by the rector on July 16th.

ROYAL COLLEGE OF SURGEONS IN IRELAND: FELLOWSHIP EXAMINATION.—Mr. C. W. H. Fleming, L.M. and S. Dublin University, having passed the necessary examination has been admitted a Fellow of the College. Miss S. H. Commissariat, L.M. and S. Bombay University, has passed the primary part of the Fellowship examination.

DONATIONS AND BEQUESTS.—Mr. John Hunter, the President of the Exmouth Cottage Hospital, has given £500 towards the funds of that institution.—Mr. A. Barlow of Southampton has given a donation of £3500 to the Royal South Hants and Southampton Hospital. Within the last few years Mr. Barlow has given £10,000 to this institution.

PRESENTATION TO A MEDICAL PRACTITIONER.—At the Oxford-street Schoolroom, Totterdown, on July 22nd, the members of the Totterdown (Bristol) and District Branch of the City and Marine Ambulance Corps presented Mr. J. J. Scammell Lucas, B.A. Lond., L.R.C.P. Lond., M.R.C.S. Eng., with a silver cigarette case, suitably engraved, as a mark of appreciation of his services as honorary instructor.

LONDON SCHOOL OF TROPICAL MEDICINE.—The following students who attended the school during the session from May to July, 1904, have passed the examination at the end of the course with distinction: J. Currie (Colonial Service), A. King (Colonial Service), E. Maples (Colonial Service), P. N. Gerrard (Colonial Service), and C. A. Suvoong.

WESTERN OPHTHALMIC HOSPITAL, MARYLEBONE-ROAD, W.—A new out-patient department has been built at this institution at a cost of £3800. This was opened recently by the Marquis of Ripon, K.G., the President, who was supported on the platform by Mr. Diggle, J.P., the chairman of the committee, Sir Reginald Hanson, Bart., the treasurer, and Sir Anderson Critchett. This department, which is now brought up to date and fitted up in the most improved style, will greatly facilitate the work connected with the out-patients who have so largely increased during the last few years. The committee hopes before long to be in a position to rebuild the in-patients' department and so to make the hospital complete in every way.

LITERARY INTELLIGENCE.—The seventh edition of Dr. Frederick Taylor's "Practice of Medicine" will be published immediately. The work has been subjected to a very thorough revision since the last edition and considerable alterations and additions have been made, especially in the sections on influenza, malaria, dysentery, the examination of the nervous system, spinal sclerosis, myoclonus, the treatment of phthisis, arterial degenerations, gastric disorders, diseases of the pancreas and of the blood, Glénard's disease, nephritis and diabetes. Other subjects are now introduced for the first time into the book which will be issued by Messrs. J. and A. Churchill. The same publishers also announce a new book by Dr. Thomas Carruthers entitled "Urine Examination made Easy, a Method of examining Urine with the Common Tests fully Described"; and a work "On the Development and Anatomy [illegible] with an Account of its [illegible] rgical Treatment," by Mr. [illegible] This is the successful Heath scholarship prize essay.

COMPLIMENTARY DINNER TO A MEDICAL PRACTITIONER.—A complimentary dinner was given on July 19th at Bedford to Dr. George P. Goldsmith by the medical men of Bedford and its neighbourhood in order to express to him their esteem and goodwill on his retirement from practice in Bedford after more than 40 years' service and on his departure from the town. 20 medical men sat down to dinner while nearly 20 regretted their enforced absence and joined in the general expression of esteem. Dr. Rowland H. Coombs occupied the chair. The menu was interspersed with some striking Latin epigrams. Dr. Goldsmith went to Bedford as a young man and has seen great changes in the town. He gave his services to the hospital for more than 30 years, when he was made consulting physician, and was first president of the Bedford Medical Society. For some years he represented the archdeaconry at the Diocesan Conference and he was a member of the elementary school board throughout its existence, and subsequently a co-opted member of the school committee. It is also intended to present Dr. Goldsmith with a Greek Testament, a Hebrew lexicon, and other works which will be valuable to him.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Alcohol for Industrial Purposes.

IN the debate on the Finance Bill the Chancellor of the Exchequer said that he had seen enough to convince him that the possible use of alcohol in manufactures had increased very considerably in recent years and that much development would follow. He was anxious to remove obstacles to enterprise in this country and he had decided to appoint a departmental committee to inquire into the whole subject.

OLVER, THOMAS, L.R.C.P. Lond., M.R.C.S., has been appointed to the Medical Charge of the Troops at Crownhill, South Devon.

ORCHARD, ALBERT JOHN, M.B., Ch.M. Edin., has been appointed Public Vaccinator for Christchurch, New Zealand.

PAYNE, J. W., M.R.C.S., L.S.A., has been appointed Port Officer of Health for Devonport, Tasmania.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

AYR DISTRICT ASYLUM.—Junior Medical Officer, unmarried. Salary £120, with board, apartments, attendance, and washing.

BRIGHTON THROAT AND EAR HOSPITAL, Church-street, Queen's-road.—Non-Resident House Surgeon for six months, renewable. Salary at rate of £75 per annum.

BRISTOL ROYAL INFIRMARY.—Resident Junior House Surgeon and Anæsthetist. Also Resident Casualty Officer. Salaries at rate of £50 per annum, with, board, lodging, and washing.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Assistant House Surgeon. Salary £60 per annum, with rooms, board, washing, and attendance.

DARENTH ASYLUM, Dartford, Kent.—Two Resident Medical Officers (Locum Tenens). Salary £4 4*s*. per week.

DEVONPORT ROYAL ALBERT HOSPITAL.—Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician, also House Surgeon, both for six months, and unmarried. Salary in each case £20, with board and residence.

HUMBERSTONE ASYLUM, Leicester.—Assistant Medical Officer. Salary £200 per annum, with furnished quarters and board.

INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Junior House Surgeon. Salary £75 per annum, with residence, board, and washing.

KENT COUNTY LUNATIC ASYLUM, Barming Heath, near Maidstone.—Chief Medical Officer and Superintendent. Salary £800, with unfurnished house, &c.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood.—Resident Medical Officer for the Country Branch Hospital at Northwood, Middlesex. Honorarium £80, with board and residence. Also Honorary Dental Surgeon.

NORTH CAMBRIDGESHIRE HOSPITAL, Wisbech.—Resident Medical Officer, unmarried. Salary £100 per annum, with furnished rooms, attendance, coals, gas, and washing.

[illegible] AND DISPENSARY.—Senior House Surgeon. [illegible] am, with rooms, commons, and washing.

[illegible] AL AND EYE INFIRMARY, Devonport.—Assistant [illegible] lary at rate of £50 a year.

ST. MARY'S HOSPITAL FOR SICK CHILDREN, Plaistow, E.—Assistant Resident Medical Officer for six months. Salary at rate of £80 per annum, with board, residence, and laundry.

SOUTH SHIELDS, COUNTY BOROUGH OF.—Medical Officer of Health. Salary £300 per annum, rising to £500.

SOUTH UIST PARISH.—Medical Officer and Public Vaccinator. Salary £77 10*s*.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Junior House Surgeon. Salary £50 per annum, with board, lodging, washing, and attendance.

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon for six months. Salary at rate of £75 per annum, with board, residence, &c.

WEST RIDING ASYLUM, Wakefield.—Locum Tenens for two or three months. Salary £3 3*s*. per week, with residence, board, &c.

Births, Marriages, and Deaths.

BIRTHS.

HAVELOCK.—On July 21st, at Sunnyside, Montrose, N.B., the wife of John G. Havelock, M.D., of a son.

LIGHT.—On July 21st, at Tillingham, near Southminster, Essex, the wife of Leonard W. Light, M.R.C.S., L.R.C.P. Lond., of a son.

PRINCE.—On July 14th, at Reigate, the wife of Peregrine C. Prince, M.R.C.S., L.R.C.P., of a son.

MARRIAGE.

THOMAS—ATKINSON.—On July 20th, at St. Mary's Church, Handsworth, Yorks, by the Rev. Francis Atkinson, M.A., Rector of St. Mary's, Birnam, N.B., uncle of the bride, assisted by the Rev. Cyril Walker, M.A., curate of Averham, Notts, and by the Rev. James Mowat, M.A., rector of the parish, George Crewdson Thomas, M.D., M.R.C.P., of Sydenham, only son of George E. Thomas, of Swainswick, Bath, to Eveline Mary, elder daughter of William Atkinson, The Birklands, Handsworth.

DEATHS.

GLASSINGTON.—On July 25th, suddenly, at 6, Pelham-crescent, S.W., Louise, the dear little wife of Charles W. Glassington, M.R.C.S., L.D.S.

SIMON.—On July 23rd, at Kensington-square, in the 88th year of his age, Sir John Simon, K.C.B., F.R.S.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

WHAT IS THE PROPER REPLY?

A CORRESPONDENT has asked us how he should reply to the following letter which has been addressed to himself and his partners by a gentleman who has started in the neighbourhood as an "optologist":—

> GENTLEMEN,—Having been successfully examined by Dr. Andrew Wilson, Dr. E. H. Tipper, Mr. J. T. Gradon, M.A., and Dr. E. H. Cook, D.Sc. Lond., who are the examiners to the British Optical Association, I am writing to ask if you would help me by sending any cases of defective vision which can be corrected by refraction. I have had a room fitted up over Mr. ——'s pharmacy solely for sight-testing and have the most modern apparatus. The two main points of the above association are: 1. To protect the public against unscientific persons who prescribe glasses. 2. That its men are so trained that they know directly should medical advice be necessary. I am, yours faithfully,

The writer incloses a card in which he styles himself M.P.S., D.B.O.A., and "optologist." We do not think the communication requires any reply. The "optologist" can be used as an optician if his services are wanted, but he must be careful not to practise ophthalmology, an integral branch of medicine, without medical knowledge.

REMARKABLE PHENOMENON OF CRYSTALLISATION.

THE *Scientific American* of July 16th states that a curious phenomenon was observed lately by Professor Stanislas Meunier of the University of Paris He found that a certain number of plaster balls left to dry [illegible] into [illegible] reached one-fifth of an inch in length. In an account of this phenomenon which he gave to the Académie des Sciences he states that although the balls of plaster had been formed under quite similar conditions and even used in the same experiments they were far from showing the same crystalline appearance. In some of them a glass was needed to see the crystals, while in others they could be distinguished with the naked eye and were from 0·2 to 0·25 inch long. Some of the specimens showed a radial arrangement of the crystals which is not seen in the natural plaster stone. The crystalline structure varies with the distance from the surface in the same ball. It is scarcely noticeable on the surface and the ball must be broken in order to observe it. When broken in halves the crystallisation is more strongly marked near the centre than in the outer parts. At the periphery there is a compact coating or skin about one-thirtieth of an inch thick. Starting from this the mass assumes the character of an irregular assemblage of crystals, more or less coherent, which often fall apart at the least shock.

GLYCEROPHOSPHATES.

IN the analytical notices on p. 226 of THE LANCET of July 23rd it was stated that the glycerophosphates of calcium, iron, and sodium of Messrs. Burroughs, Wellcome, and Co. could be had in tabloid form. As a matter of fact, the preparations sent to us were pure specimens of the salts for prescribing purposes.

A WARNING.

To the Editors of THE LANCET.

SIRS,—On Monday, July 25th, a young man of German appearance was shown into my waiting-room and said that he wished to make an appointment for me to see "Countess Reichenstein" either at my house or at a hotel in Kensington next day. She had been recommended to me by a doctor in Southampton. The appointment was duly made. The same afternoon two pieces of silver were found to be missing from my room. The police are now searching for my friend. He is about 5 feet 7 inches in height, aged about twenty-two years, pale, rather spotty face, clean-shaven or very light moustache, slight build, wore a dark short coat, and carried a light grey overcoat on his left arm, and carried two books under the other. He spoke with a strong foreign accent. If any of your readers are visited by this gentleman they are requested to inform the police.

I am, Sirs, yours faithfully,

Buckingham-gate, S.W., July 28th, 1904. H. A. DES VŒUX.

THROMBOSIS AS A SEQUEL OF APPENDICITIS.

A CORRESPONDENT writes:—"Viator" will find the subject referred to in the English edition of Nothnagel's "Diseases of the Intestines and Peritoneum," p. 898, where 400 cases of appendicitis at St. George's Hospital are quoted from. In these 400 cases, which were analysed by Mr. B. N. Tebbs, there were eight examples of thrombosis in the legs. The subject is important from the liability to pulmonary embolism after appendicitis. The thrombosis may be due to extension of inflammation to the right external iliac vein. But it is almost, if not quite, as common on the left side and may then be due to micro-organisms settling in the vein wall, which they have reached by the blood stream, and setting up first phlebitis and then thrombosis. Another bearing of thrombosis after appendicitis is that it may by embolism give rise to pleurisy.

P. C S—The number of rejections at the examination in question was not unprecedently large As far as chemistry is concerned it was considerably less than at the corresponding examination of last year though rather more than at the April examination of 1902

A J A—We shall be glad to support any such appeal, but how is our correspondent going to make sure that his bark will be followed by a bite?

Permille vires—We have no knowledge of the researches in question but we will make inquiries for our correspondent.

Medical Diary for the ensuing Week.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR AND IF POSSIBLE OF THE ARTICLE SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed To the Sub Editor

Letters relating to the publication sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET

THE Index to Vol I of 1904, which was completed with the issue of June 25th, and the Title page to the Volume, were given in THE LANCET of July 2nd

VOLUMES AND CASES

VOLUMES for the first half of the year 1904 are now ready Bound in cloth, gilt lettered, price 18*s*, carriage extra

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s*, by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates, on this or on any other ground, should be resisted The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

An original and novel feature of "The Lancet General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in The Lancet.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies *only* should be forwarded.

Cheques and Post Office Orders (crossed "*London and Westminster Bank, Westminster Branch*") should be made payable to the Manager, Mr. Charles Good, The Lancet Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

The Lancet can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

Address in Surgery

ON

THE CEREBRAL INVASION OF PATHOGENIC AND PYOGENIC ORGANISMS

AND ON

THE CHOICE OF LIGATURES.

Delivered at the Annual Meeting of the British Medical Association at Oxford on July 28th, 1904,

By Sir WILLIAM MACEWEN, M.D. Glasg., F.R.S.,

REGIUS PROFESSOR OF SURGERY IN THE UNIVERSITY OF GLASGOW.

Mr. President and Gentlemen,—Several points concerning cerebral invasion of pathogenic and pyogenic organisms have previously been brought to the notice of the profession in various communications by me, especially in a work on "Pyogenic Diseases of the Brain and Spinal Cord," published in 1893, and in the inaugural course of Lane lectures given by me in San Francisco in 1896. Subsequent experience, though modifying somewhat, has mainly confirmed and emphasised previous observations.

LOCALISATION OF BRAIN ABSCESS ARISING FROM PRIMARY PYOGENIC CRANIAL LESIONS.

The first point refers to the localisation of brain abscess. Prior to the advent of cerebro-spinal surgery in its later development, abscess of the brain was regarded solely as of a pyæmic nature, occurring by metastasis and, owing to the aberrant manner in which abscess formed, its localisation was regarded as impossible, except in the few instances where abscess happened to occur in parts which gave rise to functional manifestations. Even where abscess occurred as secondary to a primary pyogenic cranial lesion some were inclined to believe that the brain abscess was equally due to a pyæmic manifestation and accordingly could occur at any part of the brain distant from, and without relation to, the primary lesion.

Such was the old view, but early observation showed that this view was untenable. It was seen that all brain abscesses arising from the foci within the cranium were, if not in direct contact with such foci, at least in contact with the infected path which lay between the primary focus and the abscess. Knowing the primary cranial pyogenic focus *one could count upon the abscess being situated within a* circumscribed radius of that point. Subsequent experience has abundantly confirmed this view and shows that in the great majority of instances in which abscess of the brain has formed from primary foci on the exterior of the skull the brain abscess is situated in direct contiguity with the infected structures. Anatomical features, or the results of prior pathological processes, usually determine the particular direction in which the pyogenic organisms proceed from the primary focus to the brain. If the cerebral abscess remains unrelieved and continues to grow it may by extension implicate other regions of the brain distant from the primary external focus; even then the contiguity of diseased structure is generally traceable. So that, by way of illustration, if one takes intracranial abscess resulting from ear disease, one knows that such abscess will form within a limited area of the middle ear, the particular direction of the extension being determined by the anatomical condition of the parts and the direction of the prior pathological encroachments. The abscess will be found either within the temporo-sphenoidal lobe contiguous with the infected tissue round the sigmoid sinus or in the cerebrum in touch with the infected path from the tegmen antri or tympani, the pathological processes having generally prepared the way and having left in most instances an easily traceable path. This being correct, it must be apparent in a case of abscess of the brain that the preliminary investigation is facilitated and the treatment simplified, as access to the abscess in either position may be had by extension of the aperture already made in the mastoid.

THE DETERMINATION OF ABSCESS VERSUS MENINGITIS.

Anatomical features are often secondary determining factors between abscess and meningitis, and in the latter case between localised and generalised lesions. If the access of the pyogenic organisms has been by way of the tegmen or the sigmoid, abscess of the brain or cerebellum is frequent; and if meningitis results it is at least primarily localised, often the result of a soldering process, does not immediately involve vital structures, and is often amenable to prompt treatment.

ABSCESS DOES NOT OCCUR BY PYOGENIC ORGANISMS TRAVELLING BY WAY OF THE INTERNAL AUDITORY MEATUS.

If, on the other hand, the pyogenic organisms have travelled by way of the internal auditory meatus they occasion leptomeningitis of a serious kind on account of its being basal, early involving the medulla and respiratory centres; and, secondly, on account of its inaccessibility. *Abscess of the brain seldom or never occurs by pyogenic* organisms travelling by way of the internal auditory meatus. My own personal observation has never shown me a single instance of such an occurrence, nor would it be likely to occur from the anatomical features of the parts. The brain is kept apart from the original pyogenic focus by the whole length of the internal auditory canal, while the expansion of the brain membranes which ensheath the nerves in the canal dip right into it. The leptomeningitis is thus set up in the canal and from there spreads over the basal membranes. Collections of purulent matter are frequently in the meshes of the pia mater and arachnoid and occasionally they produce a softening and ulceration of the brain surface but not abscess of the brain.

TUBERCLE OF THE MIDDLE EAR EXTENDING TO THE BRAIN, THE MEMBRANA TYMPANI REMAINING INTACT.

Tuberculous meningitis has occurred in ten cases seen by me in which the middle ear was involved without perforation of the tympanic membrane and in the majority without swelling over the mastoid. In five the internal auditory meatus was the channel by which the tubercle spread from the middle ear to the membranes covering the cerebellar fossa and the basal ganglia, and these parts were so clearly and extensively involved that no attempt was made by way of operation to follow the disease after removing the primary focus from the middle ear and its adnexa. Those five succumbed to the tuberculous meningitis after various periods, some lingering for months. In five other cases intracranial operations were performed as the meningitis was unilateral and it was hoped to be still localised and to have spread by way of the tegmen. In the first of these that hope was not realised, the disease having spread beyond the possibilities of recovery. In the second the disease had spread toward the base beyond the limits of what was deemed prudent to follow. In this case, though the disease had spread through the tegmen antri and tympani, it had advanced too far and radiated in many directions. The patient improved after the operation and lived in the possession of a fair amount of health, sufficient to enable him to resume work and have a limited enjoyment of life for three years, with two meningeal attacks of short duration in the interval. At the expiry of this time his health markedly declined and he died in a fourth attack of typical basal tuberculous meningitis. In the other three cases which came under observation at an earlier period of the disease the meningitis was confined to the basi-membranes and lateral aspects of the temporo-sphenoidal lobe and were dealt with successfully, the patients not only recovering from the operation but regaining strength and vigour. The mental capacity of one of these has been sufficient to enable him to gain a foremost place in a large public school. Another instance of tuberculous meningitis (the eleventh) originating in a tuberculous lesion in the middle ear without rupture of the membrana tympani occurred in a gentleman who was only seen by me in the advanced stage of the disease, while comatose, and consequently when the usual avenues whereby information may be gleaned from the patient were closed. The only item of history that could be taken as connecting the ear with the disease was the fact that some months previously, while in Algiers, he had taken cold in the head and had complained of slight pain in his right ear, which passed off in a few days without occasioning any discharge through the external ear. When seen by me the membrana tympani was intact but somewhat wash-leather like, and slight wincing was elicited by pressure over the right mastoid region, while like pressure was tolerated over the left mastoid. There was just a possibility of affording relief by operation. The mastoid was found filled with tuberculous granulation tissue way through." Secondly, the introduction of the gut into tissues deprived of their vascularity or the vitality of which is otherwise lowered. The catgut suture remains for long periods unacted on in the midst of a slough, the leucocytes not being able to penetrate the tissue to reach the gut. Thirdly, repeated movement of a stitch after introduction breaks the connexion of the suture with the living parts and prevents leucocytal penetration; so that if the catgut thread be moved frequently in the tissues the leucocytes cannot exert their living action in the gut and therefore it remains unabsorbed. Fourthly, septicity in a wound retards absorption by weakening the tissues and by degenerating and destroying the leucocytes. When gut becomes infiltrated by pyogenic organisms and their ptomaines, as well as by pus corpuscles, it becomes more resistant to absorption and may ultimately be extruded. An impervious suture answers better in the midst of suppuration. It is evident that not only an aseptic suture must be used, but it must be introduced into an aseptic wound before one can secure the advantages of such gut. If catgut be introduced into a collection of fluid in the midst of the living tissue such as blood, serum, or pus, they will remain for weeks macerated but still intact. If the gut should, however, come into contact with the living tissue at the side of such a collection, some erosion of the part of the foreign body in contact with the tissue would ensue. It is evident that mere maceration in the tissue does not account for absorption of the catgut.

THE MODE OF ABSORPTION OF CATGUT.

Twenty-four hours after the catgut has been placed in the tissues it is found to be surrounded by leucocytes which closely invest the gut and thereafter sooner or later, according to its resistant power, gradually erode its surface and penetrate into its interior. The strands of gut in contact with these leucocytes gradually undergo erosion and appear rough and pitted on the surface. At the same time many of the leucocytes in the vicinity of the gut become swollen and take on the colour of the catgut. Between these swollen leucocytes and the strands of gut fresh leucocytes appear in the vicinity, gradually taking the place of the swollen cells. The swollen cells seem as if they had absorbed portions of the catgut and were in process of ingesting it. Such swollen cells, marked by their size and discolouration, may occasionally be seen at a considerable distance from the catgut, as if they had wandered from the scene, either by their own amœboid action or were aided or pushed aside by the movements of the fresh cells going to the attack. Occasionally the swollen cells appear so bloated that a doubt arises whether for the time at least their amœboid power had diminished or was in abeyance. The principal invasion and erosion of the catgut thread is from the periphery which results in the thinning of the thread, it being by-and-by attenuated to a mere film which rapidly disappears. While this peripheral erosion is proceeding the absorption is further aided by the activity of the penetrating leucocytes which surround and detach minute portions from the periphery which are speedily devoured. The absorption of the catgut is due to the action of the living cells and therefore is dependent on their presence and on the facilities which are afforded them for acting on the catgut undisturbed. After absorption of the catgut has proceeded for some time, and while the absorption of other parts of the gut is still proceeding, an infiltration of embryonic connective tissue cells begins to appear which forms the nucleus of a new fibrous tissue which in attenuated form ultimately remains, marking the place of the foreign body. The amount of connective tissue which forms depends somewhat on the vascularity of the living tissue and on the rapidity of absorption of the catgut. The more rapid the absorption, other things being equal, the less the connective tissue.

The use of material such as has been described is of service in facilitating wound healing. One puts into a wound just such foreign bodies as are absolutely required and these, while being sufficient to effect the purpose for which they are intended, are afterwards speedily removed by the action of the living tissues. In aseptic wounds, before the patient comes out from the influence of the anæsthetic, the surgeon has done everything necessary to enable nature to heal the wound. Its first and only dressing is applied. That dressing being of the simplest, a layer of dry sterile gauze or a film of translucent celloidin just overlapping the wound and rendering it impervious. At the end of the period deemed sufficient for wound healing this dressing may be removed, or it may be allowed to remain until it is shed, when all the external portions of the sutures are found adhering to its surface. What a comfort to be able to say at the end of an operation that in all probability there is nothing further to be done by way of handling or touching the wound which will not be looked at until it is thoroughly healed. It is no longer necessary to disturb the patient by dressing in order to remove sutures which, after they have served their function, will be silently and perfectly removed by the activity of the living cells in the patient's body. A wound which while being made is painless and remains so throughout, which heals without inflammation or the production of pus and under the dressing applied at the time of the operation, is ideally perfect.

The Croonian Lectures

ON

BRIGHT'S DISEASE AND ITS VARIETIES.

Delivered before the Royal College of Physicians of London on June 7th, 9th, 14th, and 16th, 1904,

BY *JOHN ROSE BRADFORD*, M.D., D.Sc. LOND., F.R.S.,

FELLOW OF THE COLLEGE; PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE, UNIVERSITY COLLEGE; PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

LECTURE IV.[1]

Delivered on June 16th.

CHRONIC BRIGHT'S DISEASE.

MR. PRESIDENT AND GENTLEMEN,—Having considered some of the points in connexion with acute Bright's disease and acute nephritis I will now pass on to chronic Bright's disease. The difficulties of clearly differentiating the various forms of chronic Bright's disease are undoubtedly greater than those of separating various forms of acute nephritis and acute Bright's disease. In the first place it would not seem justifiable to include degenerations of the kidney under the term of Bright's disease, although doubtless some of them clinically greatly resemble the true forms of Bright's disease. Probably all writers will agree to separating the amyloid kidney from the category of Bright's disease, although we all know that some of the forms described as the large white kidney were really instances of amyloid degeneration. Amyloid degeneration is no doubt very apt to occur associated with Bright's disease. Still, the etiology and even the clinical history of the condition are so different from those of Bright's disease that it is more convenient to treat of it as a separate entity.

One of the main difficulties in the classification of Bright's disease is the question of the position or nature of the so-called granular kidney. So many writers still include this as a definite variety of Bright's disease notwithstanding the profound differences in its morbid anatomy and especially in its clinical history from those seen in true Bright's disease. Of course, if every kidney the surface of which is granular is to be called a granular kidney, then doubtless granular kidney must be included as a form of Bright's disease, since as a matter of fact there are very few forms of chronic Bright's disease in which the surface of the kidney is not either finely or coarsely granular. A large white kidney presenting the typical smooth surface is after all not so very common, and putting aside rare forms of the disease this is the only form of chronic Bright's disease in which the surface of the organ can be said to be entirely free from irregularity. The granular kidney, or as it is preferable to call it the red granular kidney or raspberry kidney, is such a very definite renal lesion, presenting but little variation in the different specimens which we see and having such a very definite clinical history, that it certainly seems more convenient to separate it from Bright's disease. As I have already said I think only confusion is caused by grouping it with those forms of Bright's disease in which the surface of the organ is granular. The tendency of including granular kidney as a form of Bright s disease may possibly be largely due to the theoretical pathology which was in vogue some years ago and which looked upon the red granular kidney as a stage in the evolution of chronic Bright s disease No pathologist or clinician would admit at the present time that the ordinary typical red granular kidney is a final stage in the evolution of acute or chronic Bright s disease, although doubtless some forms of contracted kidney presenting a granular surface may in exceptional circumstances be such a final stage The main reasons for including the granular kidney as a form of Bright s disease are probably the fact that in some instances it may have a tox extent have a similar etic nd secondly, that some of t the body are similar to those seen in Bright s disease Thus putting aside the cardio vascular changes which may or may not be the result of a granular kidney uræmia is sometimes seen as a complication of the true granular kidney, and the same is true of certain inflammatory complications such as pericarditis, although both uræmia and those inflammatory complications are much more typical complications of true Bright s disease

---

[1] *Lectures I., II., and III.* were published in THE LANCET of July 16th (p. 125), 23rd (p. 191), and 30th (p. 283), 1904, respectively.

If arguments such as these are valid in order to justify the inclusion of the granular kidney as a form of Bright s disease similar arguments might justify the inclusion of such widely divergent lesions as the amyloid kidney or the cystic kidney and then the term Bright s disease would simply become a label for almost any condition in which albuminuria and dropsy and uræmia were present For those reasons the granular kidney will not be considered a variety of Bright s disease At first sight it may seem desirable to look upon the lesions found in the granular kidney as part and parcel of a widespread arterial degeneration and this in a considerable number of cases is no doubt true and more especially in those where notwithstanding the presence of very extensive arterial lesions the kidneys although granular are still large Probably all pathologists would agree that this form of granular kidney might with justice be looked upon as part of a widespread degeneration The difficulties alluded to above present themselves with the small red granular kidney In this form of the lesion the general arterial changes are frequently as well marked as in the other variety but this is not invariably the case and there are therefore difficulties in looking upon this form of granular kidney as merely a later stage in the evolution of the other and this justifies to some extent the opinion that such a lesion may be primarily renal

Putting on one side the true red granular kidney two fundamental varieties of chronic Bright s disease may be recognised The differences between the two forms are seen in the morbid anatomy and more especially in the clinical history and course of the disease It is possible that there may be differences in the etiology, but there is so much uncertainty at present as regards the etiology of Bright s disease generally that it is not possible to be confident with regard to this In the first form of chronic Bright s disease hich are usually kidney, although which the kidney is really entitled to be called large or where there is much increase in size are not very numerous Such kidneys are usually a little above the normal size but as just mentioned the increase may be much more considerable than this the weight of the organ may be twice or even three times that of the normal kidn and this is espe tions of the cor degree of pallor portion, however is congested and its colour affords a contrast to that of the surrounding cortex The capsule strips readily and leaves the well known smooth and somewhat marbled surface On microscopical examination such a kidney presents changes in the glomeruli in the tubules and in the interstitial tissue varying in their degree of severity and also in the relative incidence on these three sets of structures The epithelium of the glomerular chamber often shows signs of proliferation The epithelium of the tubules usually presents profound changes being shed in places and having lost its characteristic structure in others and being replaced in others by a layer of glass like hyaline cells The tubules themselves are dilated and more or less obstructed by the débris formed by the separated epithelium Casts are numerous and extravasations of blood may frequently be seen not only in the interstitial tissue but also in some of the tubules The interstitial connective tissue is increased in amount and in some of the instances where the kidneys oth the increase in the con very considerable in amount ve sels of the glomerular tuft is commonly present and it is by no means unusual to find young connective tissue in increased amount in the glomerular tuft The lesions found in what is usually spoken of as the large white kidney no doubt differ in different cases in their relative incidence but owing to all the elements of the kidney being affected the lesion may be well described as a diffuse one and there is something to be said for the term chronic diffuse nephritis sometimes applied to these cases

In the second form of chronic Bright s disease, to which it is somewhat difficult to apply a name but which may perhaps be called for purposes of simplicity the contracted white kidney the organ is very much smaller than normal, rivalling the granular kidney in size and sometimes weighing as little as from one and a half to two ounces, the colour both of the surface and of the organ on section may vary but it is usually of an opaque whitish yellow but very commonly with areas here and there of congestion so as to produce especially on the surface of the organ a mottled appearance The capsule is usually markedly thickened and sometimes very considerably so On stripping it leaves a coarsely granular surface the granulations being of large size and extremely well marked The stripping of the capsule does not commonly lead to much tearing of the renal substance and very often to none at all The cortex is greatly diminished in amount and may even be reduced to one sixteenth of an inch on section The reduction in the amount but at the same time is not section of the cortex presents con appearance the pyramidal portion of the kidney like that of the large white kidney is usually somewhat congested but not to the same marked extent so that the contrast between the cortex and the medulla which is such a striking phenomenon in the large white kidney is not nearly so obvious in the contracted white kidney On microscopic examination the most striking phenomena are, on the one hand the large areas in which there are but little remains of renal tissue owing to the very great overgrowth of fibrous tissue Many of the tubules have lost their epithelium and the great diminution in the size of the kidney is very largely dependent on such shedding and on the subsequent collapse of the walls of the tubules In some areas may be found more or less extensive remains of renal tubules with the epithelium but comparatively little altered In others the tubules are lined by hyaline and glass like cells and it is by no means uncommon to find here and there dilated tubules lined with pavement like epithelium approaching to the character of cysts The glomerular chamber is thickened and the vessels of the tuft present marked changes both in the hyaline degeneration and in the fibroid overgrowth There is a very great overgrowth of the interstitial tissue of the kidney generally and areas are found scattered over the kidney consisting of but little except fibrous tissue The microscopic appearances of such a kidney present points of resemblance to those seen in the true granular kidney On the whole it may be said that the overgrowth of fibrous tissue in the contracted white kidney is more uniform than that seen in the true granular kidney and that the epithelial changes are more marked Further, in the contracted white kidney the arterial lesions only exceptionally reach the high degree of development seen in the true granular kidney and this is not only true of the arterial lesions of the ve els of the body generally but also of those in the kidney

There are therefore marked differences in the macroscopic and microscopic appearances of the large white and of the contracted white kidney of Bright s disease in typical instances of the two diseases But considerable difficulty is often experienced in correctly placing some forms of chronic Bright s disease Thus very exceptionally kidneys are found very small in size and resembling in that respect the contracted white kidney, but on the other hand quite smooth on the surface and showing no great overgrowth of fibrous tissue and it is difficult to classify such instances as the c Again kidneys presenting many of the features of the contracted white kidney but of a somewhat larger size but always less than the normal are seen. In these instances it is very common for the granulations on the surface seen on stripping the cortex to be smaller than those seen in the typical form of the contracted white kidney. It is owing to differences such as these in certain instances of the disease that the view has been advanced that all these forms of chronic Bright's disease are really stages in the evolution of one and the same malady and if our attention is confined to the study of the facts of the deadhouse there is no doubt much to be said for this view. Many pathologists who have absolutely given up the theory that the true red granular kidney is a final stage in the life-history of Bright's disease still hold the view that the contracted white kidney is the sequel to the large white kidney and that the large white kidney is a sequel of acute Bright's disease. In other words, they consider that there are, so to say, two forms of interstitial nephritis, one the sequel of chronic parenchymatous and tubular nephritis and the other associated with the widespread arterial degeneration known as the true granular kidney. Others have attempted to overcome the great difficulties in the interpretation of these cases by suggesting that in some instances of the contracted white kidney we are really dealing with the true red granular kidney in which a subacute tubular nephritis has occurred as a complication.

In addition to looking upon the contracted white kidney as a sequel of the large white kidney or as a true granular kidney with an acute or subacute nephritis superimposed there are at least two other modes of origin for this variety of renal disease. It might be regarded as a sequel of acute nephritis or on the other hand it might be a definite variety of Bright's disease, that is to say, a form of malady maintaining its individuality throughout its evolution. These difficulties as regards the correct interpretation of this very definite form of renal disease cannot, I think, be determined solely from considerations based on the morbid anatomy of the disease, but the clinical history of Bright's disease must also be taken into account. Even on grounds afforded by the study of morbid anatomy it is improbable that contracted white kidney can be looked upon as a true granular kidney with a subacute nephritis superimposed. The interstitial overgrowth is far more irregularly distributed in the red granular kidney, so that the pattern of a microscopic section is different, and by these means sections of these two forms of renal disease may often be readily differentiated. Further, the arterial lesions in the renal vessels of the red granular kidney, and especially the endarteritis, are very much more marked, although, of course, it must be admitted that in most instances of the contracted white kidney somewhat similar arterial lesions are found to a considerable degree of development both in the renal vessels and those of the body at large. The contracted white kidney, however, may occur and cause death from uræmia without the arterial lesions in the body generally reaching the high degree of development that we associate with the red granular kidney. In some instances of very advanced forms of this lesion neither the arteries generally nor the heart present any marked changes, such as endarteritis and hypertrophy. This absence of cardiac hypertrophy in some forms of chronic Bright's disease, not only where the kidneys are large but also where they are small and fibroid, has led some writers to differentiate these cases as a definite variety under the term of aplasic Bright's disease.

The conditions determining the absence of cardio-vascular changes in cases of contracted white kidney are unknown. It can scarcely be dependent, as has been suggested, on an incapacity on the part of the tissues to respond to a stimulus, inasmuch as this absence of cardio-vascular changes is not uncommonly seen in the most advanced and typical forms of the contracted white kidney occurring in young adults. This affords, I think, a point of distinction between the contracted white kidney and the true granular kidney, since in the former it is not uncommon to meet instances where not only the vascular lesions are ill-developed in the general vessels of the body but the cardiac hypertrophy may be absent, whereas in the latter, the true granular kidney, it is certainly extremely rare, if not unknown, to find a renal lesion except as part and parcel of a widespread arterial degeneration, and it is more common to find the lesions in the heart and in the blood-vessels generally advanced to a high degree with the renal lesions comparatively slight than to find the converse.

Another line of argument that may be advanced in order to discriminate between the contracted white kidney and the granular kidney is that the former on microscopic examination does not show any changes that can be looked upon as indicative of the presence of an acute nephritis. In many instances the disease causes death more or less suddenly or after a short illness in patients who may have maintained apparently good health until very shortly before their last illness, yet even in these instances the microscopic appearances of the kidney show essentially chronic changes. On these grounds, therefore, quite apart from the clinical history of the cases which we will consider later, I see no reason for looking upon the contracted white kidney as a red granular kidney in which a subacute or acute nephritis has occurred as a complication. There is undoubtedly more to be said on morbid anatomy grounds for looking upon this lesion as a sequel of the large white kidney. The great diminution in the size of the organ in the contracted white kidney is no doubt largely dependent on the shedding of the tubular epithelium and the practical disappearance of large areas of renal tubules; and of course it must be admitted that kidneys presenting the appearance of the large white kidney are seen of all sizes, so that it would not be difficult to collect a series of cases from the most extreme large white kidney on the one hand to the extreme contracted white kidney on the other hand. In the large white kidney there is an overgrowth of fibrous tissue varying in amount and the greater amount present in the contracted white kidney might be looked upon as a result of a progressive change possibly associated with the destruction of the epithelium. Further, the arterial system and the heart do undergo changes, as is well known, in the large white kidney and therefore these also might be accounted for.

Confining ourselves, however, strictly to the morbid anatomy of the two diseases there are objections to accepting this view. In the first place, it is definitely known that the large white kidney may remain large for many years. Hence the conversion of the large white into the contracted white kidney could not at any rate be a normal or a necessary sequel. The overgrowth of connective tissue present in the large white kidney would seem to be associated with the finely granular appearance of the surface of the cortex. This is especially well seen in those specimens of the large white kidney which are but little above the normal kidney in size, whereas the granulations seen in the contracted white kidney have a totally different appearance owing to their large size. Further, the proliferative changes which are seen to such a remarkable degree in the glomerular chambers of the large white kidney are not, so far as my experience goes, present in the glomeruli of the contracted white kidney. It may, of course, be argued that none of these points of difference in the morbid anatomy are of sufficient importance to justify the conclusion that the one lesion is not necessarily derived from the other and, as I have already stated, I think myself that the main reason for looking upon the contracted white kidney as not necessarily dependent on, or as a sequel of, the large white kidney is to be derived from clinical rather than from morbid anatomy considerations.

The remaining question is that the contracted white kidney may possibly be the sequel of acute nephritis. This is a view that on *a priori* grounds is very probable and one which scarcely can either be proved or disproved by the morbid anatomy of the disease, so that it will be convenient to pass on to the consideration of some of the points in the clinical history of chronic Bright's disease. There can be little doubt that, from the clinical point of view, two varieties of chronic Bright's disease may be differentiated. The first is where the prominent effects are dropsy and the tendency to the occurrence of secondary infections, more especially with inflammation of various serous membranes. In the second variety of the disease the prominent effects produced are grave disturbances of nutrition, such as marked wasting and the occurrence of uræmia and especially of acute uræmia, and there is further the very marked negative characteristic that dropsy is either completely absent or at any rate very trivial in amount and it is much more common for it to be completely absent. Like all clinical distinctions these are not absolute; thus uræmia may undoubtedly occur in both forms of the disease and it might even be said that chronic and subacute uræmic symptoms are common in that form of Bright's disease in which dropsy is prominent. But the most severe forms of uræmia, known as the acute or even the fulminating, are in my opinion peculiarly associated with that form of chronic Bright's disease where dropsy is absent or ill-developed. Inflammatory complications, such as pericarditis, pleurisy, pneumonia, &c., undoubtedly occur in both varieties so that the main differentiation from a clinical *standpoint is according to the presence or absence of dropsy* and the degree and development and variety of the uræmic symptoms present. Wasting, no doubt, is oftentimes present to a very high degree in the cases where dropsy is a marked feature but it is masked by the occurrence of the dropsy and the symptoms produced by the waterlogged condition of the patient commonly mask those dependent on the disturbance of the nutrition. Wasting is probably of universal occurrence in all serious kidney diseases but it reaches a very high degree of development in some forms of chronic Bright's disease rivalling that seen in malignant disease, and from time to time cases are seen where the patient seeks advice solely on account of the progressive loss of strength and flesh and where the renal origin of the trouble may be completely overlooked by a careless observer. Although wasting is the most conspicuous disorder of nutrition produced [illegible] another remarkable effect someti[illegible]omewhat resembling the pigmen[illegible] and one of the specimens on the table of contracted white kidney is derived from a patient where the great loss of strength and of flesh and the occurrence of pigmentation with some vomiting led to the diagnosis of Addison's disease although the case was really one of contracted white kidney.

The clinical picture of ordinary chronic Bright's disease associated with dropsy is so well known that it is quite unnecessary to consider it at any length. But the other form of chronic Bright's disease is one which I am convinced is very frequently overlooked owing to the latent course the malady frequently runs and the apparent obscurity of many of the symptoms produced. One of the most puzzling features of this form of chronic Bright's disease is the fact that such a large number of the cases are seen in young persons frequently under 30 years of age not uncommonly under 25 years who state that they have had good health until perhaps a few weeks or even sometimes a few days before the onset of symptoms that are rapidly fatal. It is one of the most striking instances in medicine of a disease that is apt to run a latent course. I have known of an instance in an apparently healthy young man 25 years of age, presenting no symptoms and where the condition was discovered as a result of an examination for life insurance where death resulted from acute uræmia within a fortnight of the discovery of the existence of the albuminuria. In other cases the onset l[illegible] persons apparently in[illegible] with acute uræmia of [illegible] variety.

The forms which the uræmia *may assume in this* variety of Bright's disease are numerous and liable to give rise to considerable difficulty sometimes in the diagnosis. Thus it is not very rare for the uræmia to be of a maniacal type and hence lead to confusion between these cases really of chronic Bright's disease and acute mania. I have seen one instance where a young woman was admitted to hospital on account of cataleptic phenomena and where death resulted after a very short illness from acute uræmia. In other instances the first symptom that may attract attention is that very co[illegible]nœa leading pe[illegible] the course of a[illegible] owing to the so called asthma being really uræmic dyspnœa associated with this grave lesion of contracted white kidney. I think it may be stated that on the whole these patients are most likely to come under observation suffering from one or another of the many forms of acute or even of subacute uræmia. Although these patients are liable to present prominent uræmic symptoms during the last illness there are *other* features which are *fairly characteristic of* the second variety of chronic Bright's disease. Thus the patients are usually young generally under 35 years of age and frequently between 30 and 20 years of age and as I have already mentioned they may present marked symptoms general loss of strength with wasting or some disturbance of nutrition such as darkening of the skin. Headache may be a prominent symptom and owing to the frequent occurrence of very marked fundus changes in this variety of Bright's disease confusion with cerebral tumour or even cerebellar tumour may occur. A considerable proportion of the cases are seen in young women and these frequently present an aspect superficially resembling that of chlorosis the *resemblance being all the greater in* some instances owing to the presence of headache. Perhaps the most remarkable feature of this variety of chronic *Bright's disease is the one already slightly alluded to above,* that the disease is apt to run a more or less latent course or at any rate to produce such apparently trivial symptoms as to escape notice until the final uræmic manifestations. This is very different from what occurs in the other variety of Bright's disease where dropsy is such a marked sign and it is sometimes difficult to make patients in whom this variety of the disease is recognised as a result of complete examination to realise the gravity of the condition. The uræmic symptoms are not only very commonly present but they are the usual cause of death in other words, the acute form complicating this variety of Bright's disease is of far more serious import than the acute uræmia complicating other varieties of renal disease as for instance, acute nephritis or acute Bright's disease.

There are not only these marked differences in the clinical symptoms present in the two forms of chronic Bright's disease but the urine also presents characteristic differences in the two conditions. In that form of Bright's disease associated with dropsy the urine is necessarily diminished in quantity and contains a variable but usually large amount of albumin together with a considerable variety of casts. In the second form of chronic Bright's disease the volume of the urine is not only not diminished but is very commonly above the normal resembling in its quantity that seen in the true granular kidney. The specific gravity is low but the amount of albumin is very considerable amounting to a quarter or a third or even to a half. Casts are present of the hyaline and granular varieties but not necessarily so abundant as those seen in the other form of the disease. So far as my experience goes this form of Bright's disease is the one where there may be the maximum *loss of albumin inasmuch as there is not only a con*siderable percentage of albumin in the urine but the quantity of the latter may be increased and thus though the percentage quantity of albumin present be less than that seen in the large white kidney the total daily loss is greater owing to the great difference in the quantity of urine excreted in the two conditions. The combination of abundant or even increased excretion of urine containing a moderately high percentage of albumin is no doubt, the reason that many look upon the condition as one of the red granular kidney complicated by the supervention of acute or subacute nephritis but we have already seen anatomical reasons for not accepting this conclusion.

This second form of chronic Bright's disease then is characterised by its tendency to occur in the young by the excretion of an abundant highly albuminous urine by the clinical course being either a latent one or else one where the main symptoms may be said to be those of disturbance of nutrition and most important of all by the terminal illness being of a sudden onset and characterised by the predominance of uræmic symptoms. On post mortem examination in the second variety of the disease the contracted white kidney is found. The course of the illness in this variety of Bright's disease is not only apt to be latent but very frequently these patients state that they have never suffered at any time in their life from dropsy and this to my mind is one of the main reasons for thinking that the condition is not *necessarily the sequel of the large white kidney.* In fact in the typical forms of the disease occurring especially in young women I very much doubt whether it has any relation at all to the large white kidney. It must however be admitted that we sometimes see patients dying from uræmia without the presence of dropsy where in the past dropsy has been present and in such patients chronic diffuse nephritis resembling that seen in the large white kidney may be found with perhaps rather more overgrowth *of the interstitial* fibrous tissue. Such cases however both in their clinical history and in their morbid anatomy, are not precisely *the same as those with which we are now* dealing and as has already been mentioned it is definitely known that the large white kidney may remain a large white kidney for many years. I think therefore it may be stated confidently that the contracted white kidney both from the clinical study and from the study of morbid anatomy, is not necessarily the sequel of the large white kidney.

No support is afforded by the study of the clinical symptoms to the idea that the contracted white kidney is a red granular kidney in which subacute or acute nephritis has occurred. The red granular kidney produces *fairly typical clinical* symptoms in that it occurs in elderly patients and cardio vascular symptoms form a marked feature of the illness and there is a far greater tendency for the disease to destroy life by the occurrence of such complications as cerebral hæmorrhage and for the occurrence of uræmia. It is quite true that sometimes the sudden occurrence of uræmic symptoms suggests the onset of an acute complication, but still it is characteristic for acute symptoms to arise in many chronic diseases and even to be fatal without the onset of any such acute complication. This, for instance, is seen especially in diabetes and in hepatic cirrhosis. Acetonæmia in the one and cholæmia in the other, it would seem, may occur as a result of the progressive destruction of gland tissue. In these cases of contracted white kidney the urine at the time of the occurrence of the fatal uræmia does not present any changes that could be looked upon as indicative of acute nephritis. It is by no means uncommon for large quantities of urine to be excreted during the uræmic period, although perhaps it is more usual for the quantity to be diminished. The urine is not necessarily more albuminous during the terminal stages of the illness than at earlier periods. It would seem, therefore, from the study of the morbid anatomy, from the course of the clinical symptoms, and from the characters of the urine that the contracted white kidney is a distinct entity and not necessarily related to the large white kidney or the true granular kidney. One of the remaining problems is to consider the relationship, if any, existing between this form of Bright's disease and acute affections of the kidney, such as acute nephritis or acute Bright's disease. There can be no doubt that both acute nephritis and acute Bright's disease may occur in patients who subsequently may suffer from Bright's disease in one or other of its forms, and it would be rash to deny that the contracted white kidney may sometimes have that origin. It is, however, quite certain that it may occur in persons who have never suffered from dropsy and who have never been laid up by any serious illness and it is difficult to suppose that in all these cases acute nephritis has really been present at some antecedent period and has not been recognised. Not only may no history of acute nephritis or acute Bright's disease be obtained but sometimes no history of the acute specific diseases which are the more potent causes of the renal complications can be elicited and my own feeling is that not uncommonly this form of Bright's disease may arise independently and be slowly progressive and that it is not necessarily the sequel of an acute renal infection although it is very probable that in some instances it is.

ON DIAPHRAGMATIC HERNIA OF THE STOMACH AND ON TORSION OF THE SMALL OMENTUM AND VOLVULUS OF THE STOMACH IN ASSOCIATION WITH IT.

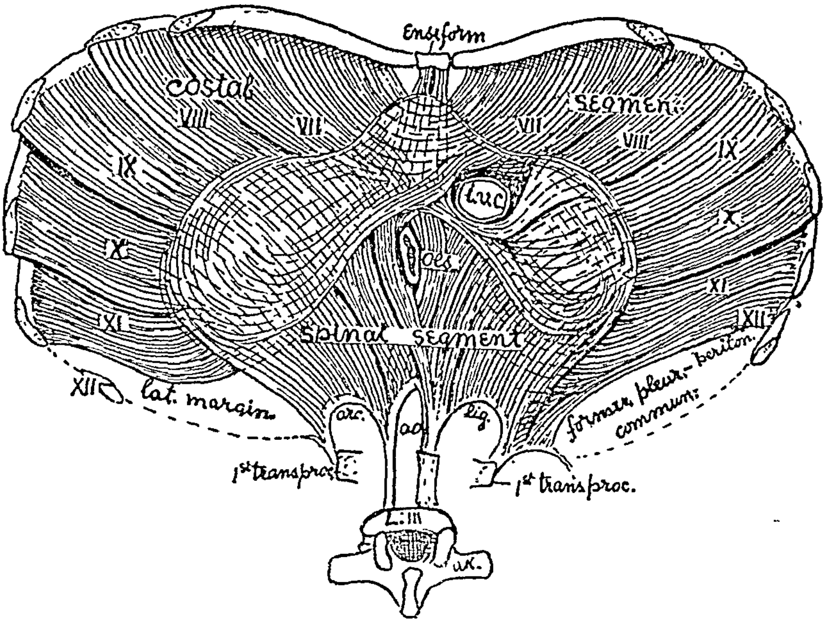
By R. LAWFORD KNAGGS, M.C., M.D. Cantab., F.R.C.S. Eng.,
SURGEON TO THE LEEDS GENERAL INFIRMARY.

A GASTRIC hernia is usually diaphragmatic. It is exceedingly rare for the stomach to be found in any of the more usual forms of external hernia, if post-operative ventral protrusions occurring above the umbilicus be excepted. But hernia of the stomach constitutes a very considerable proportion of all cases of diaphragmatic hernia and the relations of the viscus to that structure are a sufficient explanation of its relative frequency. The object of the present paper is to consider the various conditions that are met with when the stomach is engaged in such a hernia. It is based upon material derived from 63 cases.

Diaphragmatic herniæ are of three kinds: (1) congenital; (2) traumatic; and (3) acquired.

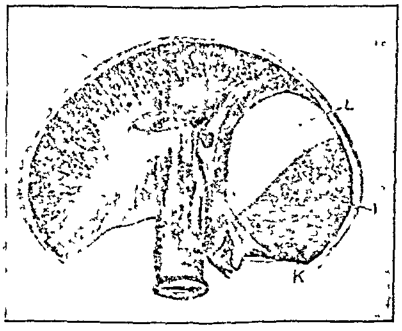
1. *Congenital.*—Congenital cases are always due to apertures in the diaphragm resulting from imperfect development. The nature of the diaphragm has been discussed by Dr. Arthur Keith in his recent Hunterian Lectures on Enteroptosis.* He points out that "in structure, in development, in evolution, and in action the diaphragm is a true digastric muscle made up of two segments—a spinal or dorsal and a costal or ventral." In man with the assumption of the erect posture the spinal segment spreads out laterally until the spinal and the costal segments almost meet (Fig. 1). In many subjects there is a fibrous interval between the origin and insertion of the diaphragm and this interval marks the site of the original communication between the pleural and peritoneal cavities and also the outer or lateral margin of the muscle. Dr. Keith states in The Lancet of March 7th, 1903, p. 635, that "congenital diaphragmatic herniæ occur between this lateral margin of the diaphragm and the costal wall and in such cases the free lateral margin of the diaphragm can be seen very distinctly." No doubt this explanation is the correct one in many cases, for instance, in those—not infrequent—in which the diaphragm is stated to have been deficient or absent on the left side (see Fig. 2)

Fig. 1.



The diaphragm spread out and viewed on its thoracic aspect. Fibres pass through the central tendon and unite the muscular fasciculi of the spinal segment to those of the costal segment. (From The Lancet of March 7th, 1903, p. 635.)

Fig. 2.



Large oval deficiency on the left side of the diaphragm in a case of congenital diaphragmatic hernia. (From Dr. Thomas Balfour's paper, *Edinburgh Medical Journal*, vol. xiv., p. 885.)

* The Lancet, March 7th and 14th, 1903.

and in one (54) in which there was a fissure between the central tendon and the cartilages But not every protrusion takes place external to the lateral margin In one the anterior portion of the diaphragm behind the sternum and the cartilages was deficient and a gap existed bounded by a tense lunar arch (48) In other cases the aperture was in the tendon

In stomach hernia the gap is in most cases on the left side but in three instances it was on the right and the presumption is, when it is not definitely stated, that the protrusion occurred into the right pleura (33, 50, 58) Of 24 congenital cases four were met with in fœtuses, five in children who died at birth, and 15 in persons whose ages varied from six weeks to 60 years

2 *Traumatic* —Of 21 cases of stomach hernia following injury seven were due to wounds, seven to crushes, six to falls, and one to "being run over" The wounds were either stabs, sword or bullet injuries Of the crushes two were "buffer accidents" and the falls were usually from a height In every instance there was an aperture and this was more frequently situated in the tendinous than in the muscular part of the diaphragm and rarely near the origin of the muscular part from the ribs In cases where the patients died soon after the injury the opening was of the nature of a tear or rent, but if the sufferer lived for some years it became a well defined aperture, sometimes with rounded, smooth, and callous edges, and not infrequently there were adhesions in its neighbourhood between adjacent parts or the viscera engaged in it The diaphragmatic wound was never fatal *per se* and the patient not infrequently survived unless there were associated injuries of a grave character

3 *Acquired* —The existence of a sac has been held by the writer to be conclusive evidence that the rupture has been acquired Eight cases fulfil this requirement Three found their way into the right chest (6, 36, 63) and four into the left (23, 31, 32, 61) The eighth case was the remarkable one recorded by Dr Bright (9) in which a membranous sac bulged into both right and left chest (Fig 3) It was

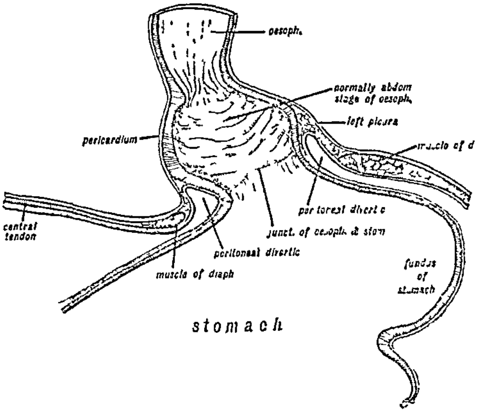
thought to
diaphragm,
der opmer
incorrect
which no statement is made as to the existence of a sac, but since the hernia took place through a dilated œsophageal opening in each case there is a strong presumption that both were acquired In another instance (44) the hernia passed through a dilated œsophageal opening Apparently there was no sac but the symptoms dated from a time when the patient "felt something rip in his inside" whilst lifting a pig of iron Lastly, there is a form of hernia of the stomach through the œsophageal opening, of which Dr Keith and Dr Rigby have recorded an example Here, owing to the descent of the diaphragm from the giving way of its supports, the cardiac orifice of the stomach comes to lie within the thorax and above the level of the muscle (37). (Fig 4) In all,

FIG 4



An example of diaphragmatic hernia of the stomach in a case of ptosis (From the proceedings of the Anatomical Society of Great Britain and Ireland and published in THE LANCET of March 7th 1903)

therefore, there were 12 cases of acquired hernia and it is of much interest to see how they were associated with certain natural weak places in the diaphragm In no less than eight (6, 21, 34, 35, 37, 44, 61, 63) the protrusion was either through, or doubtless determined by, the œsophageal aperture

Long ago Dr T Balfour pointed out that even when no hernia existed these natural foramina were occasionally found of unusual size The œsophageal foramen particularly seems to predispose to rupture and were it not that gravity exercises a contrary influence it would probably be met with oftener Indeed, its more frequent occurrence in quadrupeds has been attributed by Sir Astley Cooper to the position of their bodies There is also a weak spot on either side of the origin of the muscle from the ensiform cartilage, between that and the costal origins This gap in the muscle (Fig 1) is perforated by the superior epigastric branch of the internal mammary artery and in one case (36) the hernia followed this path It may be added that herniæ, though not of the stomach, have been known to take place through the opening transmitting the splanchnic nerve

Hernia of the stomach may be (1) complete, (2) incomplete, (3) partial or a Richter's hernia, and (4) associated with other viscera

1 *The complete form* —Of this there is not much to be said The whole stomach has passed out of the abdomen into the sac or the thoracic cavity With it there is certain to be more or less of the omentum and it may be a small portion of the duodenum The greater curvature has in some cases been said to lie uppermost

2 *The incomplete form* —In incomplete hernia of the stomach the pyloric extremity is most frequently protruded, occasionally the cardiac end, and sometimes the middle portion of the viscus The whole lumen, however, is engaged

3 *Partial or Richter's hernia of the stomach* —Here the hernia is formed by a pouch-like projection of the stomach wall and does not include the whole lumen Only two instances have been met with and in neither is there any clinical history One is recorded by Dr. C. F Andrew "A dome shaped pouch of the diaphragm existed immediately to the left of the œsophageal opening and into it a portion of the cardiac end of the stomach, measuring vertically about an inch, was drawn The hernia could easily be pulled down and the part of the stomach wall that lay against the neck of the pouch was thickened" The condition was found in the dissecting room in a female subject and had probably caused

no serious trouble during life (31). (Fig. 5.) The other is a specimen in the Guy's Hospital Museum, No. 1088. A pouch formed from the greater curvature has passed through an aperture in the diaphragm and has evidently been strangled and the cause of death (39). (Fig. 6.)

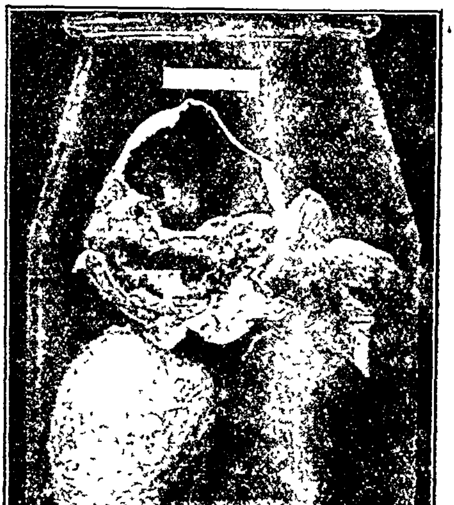
FIG. 6.



Guy's Hospital Museum, No. 1088. Diaphragmatic hernia. A portion of the diaphragm with the stomach and spleen mounted to show a smooth edged perforation of the diaphragm, measuring about two inches in diameter, through which part of the stomach and great omentum have passed into the thoracic cavity and become strangulated. Below the diaphragm the stomach is seen with its lesser curvature and its œsophageal and pyloric orifices directed downwards.

4. *Diaphragmatic hernia in which the stomach is associated with other viscera.*

Table showing the Various Associated Viscera in the Herniæ.

1. Stomach only	9 cases.
2. Stomach and part of duodenum	3 ,,
3. Stomach and omentum	5 ,,
4. Stomach and spleen	3 ,,
5. Stomach, spleen, pancreas, and colon... ...	5 ,,
6. Stomach, spleen, and transverse colon... ...	6 ,,
7. Stomach and colon	22 ,,
8. Stomach, liver, and small intestine	3 ,,
9. Stomach, spleen, liver, omentum, and small intestine (part)	2 ,,
10. Almost all abdominal viscera...	1 case.

Some interesting facts are brought out by this table. The colon, the spleen, the pancreas, and the liver are the viscera most likely to be found associated with a stomach hernia. The colon was met with 33 times, the spleen 16, and the pancreas five. The stomach was alone with the colon in 22 cases and alone with the spleen in three but the spleen and the colon were together in 11. In every case in which the pancreas was found the spleen and part of the colon were also protruded. The frequent presence of the colon, spleen, and pancreas is not to be explained by their proximity to the aperture but to their close anatomical connexions with the stomach. Thus the colon follows the stomach because it is dragged after it by the gastro-colic omentum. The cardiac end of the stomach when it leaves the abdominal cavity pulls the spleen in its wake by the gastro-splenic omentum and the vessels and fascia which it incloses, and the pancreas follows owing to its connexions with the splenic vessels and the subperitoneal fascia which accompanies the vessels into the different viscera. Consequently, as might be expected, the spleen is more frequently present than the pancreas, but the pancreas is never found without the spleen. The pancreas is the one abdominal viscus that has the credit of never having been found in a hernial sac. It may still continue to hold this record, for in all five instances it had passed through apertures or large gaps. The liver was present in all in seven cases.† The gap is usually considerable when the liver is present, but though the close proximity of the liver to the gap cannot be overlooked yet it is probable that the traction exerted upon it by the gastro-hepatic omentum is a more determining cause. The presence of the small intestine, with the exception of the first part of the duodenum, is more accidental.

PREDISPOSING AND EXCITING CAUSES.

There is nothing to add to what has already been said about congenital apertures except that in one instance (23) the defective development was attributed to "maternal impression" in the early weeks of pregnancy. The causes of traumatic cases have also been considered. In the acquired the natural foramina are an obvious predisposing condition and muscular exertion is a frequent exciting cause. Thus in the case of a weakly child (6) a severe attack of vomiting lasting several days probably induced the rupture. In another (32) excruciating pain in the left hypochondrium came on during a violent effort to escape a blow and was followed by symptoms which ended in death. In a third (11) the patient was seized with a paroxysm of coughing whilst attempting to lift a pig of iron and felt something "rip in his inside." He died five days later from strangulation of the protruded viscera. In Dr. T. Churton's and the writer's case symptoms of stomach trouble became manifest a few months after a confinement (63). There is another case (19) in which the symptoms dated from a long and tedious confinement, but a few months before the patient had received a stab which most likely wounded the diaphragm. In the interval she had recovered from the injury and had enjoyed her usual health.

In one of the congenital cases, too (15), symptoms developed after a fit of crying and the infant, who had been in perfect health before, died in 24 hours. Lastly, there is the negative pressure within the thorax during inspiration to be taken into account. This is of most importance when a hernia has already formed and one of the lungs is more or less compressed and incapable of expansion. Under such conditions it would tend to prevent spontaneous reduction of a protrusion which might in many instances occur under the favouring influence of gravity. This influence must in diaphragmatic hernia be a powerful one, as a moment's consideration of the ease with which many inguinal and femoral herniæ disappear in the recumbent posture will show. Consequently some idea may be formed of the effect likely to be exerted by the thoracic aspiration.

SYMPTOMS.

In a condition in which not only the alimentary canal but the lungs and heart are likely to be incommoded seriously very varied symptoms may be anticipated. But various and irregular as they are, yet the majority fall naturally into one or more of the following groups: (1) dyspnœa; (2) dyspepsia; (3) obstruction and strangulation; and (4) tetany. In a few cases there were no symptoms referable to the hernia (21, 38, 40) *and one case at least was found unexpectedly* (41) Great thirst has several times been noted but there was always some serious complication in the shape of other injuries or a mortal consequence of the rupture (1, 7, 24, 26)

---

† This does not appear from the table but in addition to the five cases mentioned there the liver was found in one of the spleen cases and in another where the spleen and pancreas were present.

1 *Dyspnœa* —Respiratory difficulties are very common
They may be
upon the heart
other may be c
stomach hernia the left side is nearly always affected most likely both take a share In one case in which the hernia was on the right side there was no complaint of difficulty of breathing Difficult breathing in some instances is constant and may last for years *Sometimes there is a liability to* sudden attacks at intervals More often it is brought on by exercise or going upstairs, after a full meal or when food disagrees, though ' the asthma ' of one patient was relieved when he ate In more than one case in which respiration was embarrassed there was lividity In one (2) the face would become livid during the attack and in this and another the dyspnœa ended fatally (32)

2 *Dyspepsia* —Where the hernia is chronic there is often a history of discomfort and vomiting after meals and sometimes of pain These symptoms are probably induced by the difficulty in the propulsion of food from the stomach and are associated with dilatation of that viscus, often extreme which is frequently described in *the records of the* cases

3 *Obstruction and strangulation* —The dyspeptic symptoms are only the earlier signs of obstruction which is incomplete and varying in degree, but they are very liable sooner or later to culminate in an acute attack of complete obstruction in which violent or excessive vomiting, often without retching, is accompanied by pain and constipation and terminates life in a few days It is probable that in many *of these cases a certain degree* of strangulation is present and that they gradually merge into that class of case in which there is very definite interference with the circulation

Lack of precision in description of the necropsies makes it impossible to form any real idea of the frequency with which strangulation occurs but there can be no question *that strangulation* was *the cause of death in at least* seven cases (10, 18, 43, 44, 52, 61, 63) and it is more than probable from the severity of the symptoms that it was present in six others

4 *Tetany* —In view of the attention that has been attracted of late to the association of tetany with gastric conditions the following brief report of a case under the late Sir Russell Reynolds (18) of diaphragmatic *stomach hernia* is of more than passing interest

CASE 1 —A woman, aged 29 years, had been stabbed about the seventh rib on the left side some seven years before admission to University College Hospital Though the lung was wounded she recovered good health Then she had a long and tedious confinement and never recovered strength suffering from repeated vomiting after taking food This state of affairs had gone on for six years She remained in hospital *nearly five months* without any *great change* On March 29th she was flushed and uneasy On the 30th contractions of the muscles of the forearms and arms were noticed The hands were adducted, the fingers and forearms were flexed, resisting extension and the patient could not move them Then she became unable to open her mouth and had pain in the back and mouth *The temperature* was 103 6°1 In four hours from the commencement of the spasms she died in a state of general tonic spasm At the post mortem examination the whole of the stomach with the exception of a small portion at the cardiac end was found to be displaced *together with several inches of the transverse* colon and some omentum into the left thoracic cavity through an opening near the left edge of the central tendon of the
diaphragm The hern had
displaced the heart to con
striction at the neck and
below the diaphragm

PHYSICAL SIGNS

The physical signs are very indeterminate This is only what might be expected when it is remembered that a correct diagnosis has rarely been made before a post mortem examination Signs, indeed, are often marked but the difficulty lies in their interpretation They may be divided into *(1) those of prime importance* and (2) *those of* subsidiary value

1 *Signs of prime importance* (*a*) *Stomach or intestinal noises in the chest* —The uncertainty in connexion with this sign lies in the possibility of the sounds being 'transferred " Coupled with other signs, such as absence of respiratory *murmur*, it may be almost diagnostic and, indeed it would appear that in some of the very few cases in which a diagnosis has been made during life it has been by the importance attached to them (84)

(*b*) *Intestinal peristalsis communicating writhing movements to the chest wall* —Such a sign would be of the utmost value if it were of frequent occurrence It has however, only been noted once (Holt) and in the case of a child (46) It is obvious that for it to occur the chest wall must be very supple and therefore it is only in the case of an infant that *there would be a possibility of it being seen* It was due to the intestines in Holt s case but there is no reason why stomach contractions should not be visible under similar suitable conditions

(*c*) *Displacement of the heart to the right side* —As a very large majority of all stomach herniæ occur into the left chest this is of frequent occurrence It is, of course only of value when joined to other signs

(*d*) *A respiratory bruit* In one case (Case 2, *infra*) there was heard over the left lower ribs in the posterior axillary line a peculiar blowing sound which was evidently connected with the respiratory movements Had it been *heard in the upper part of the chest it would have been* described as amphoric One auscultator described it as
e others who listened it was a
was not grasped at the time
t at the necropsy its explana
tion was obvious It was produced by the forcing of gas during expiration from the herniated portion of the stomach *into its abdominal portion through the narrow orifice caused* by the constriction at the neck of the sac It is hardly likely to occur with any other part of the alimentary canal than the stomach and with that only when a considerable portion lies in the thorax and another large portion in the abdomen It implies the existence of a patent communication between the two portions at the neck of the sac and consequently the absence of strangulation *by the neck* is a fair inference Its importance therefore, when strangulation exists will be seen when volvulus of the stomach and torsion of the small omentum are discussed for the latter of these conditions was present in the case in which it was heard

2 *Signs of subsidiary value* —(*a*) Absence of breath sounds (*b*) alterations in resonance, (*c*) changes in shape and deficient movement of the side of the chest in which the *hernia is situated* (*d*) sinking in of the epigastrium, and (*e*) inability to lie on the opposite side Of most of these it may be affirmed that they vary in degree, are by no means constant and are only of practical use as an aid of more or less value in the interpretation of some of the more important signs mentioned above

PATHOLOGY

1 *Adhesions* —Adhesions in the absence of strangulation are not very common *When they do occur they are usually* omental and in the vicinity of the aperture

2 *Chronic ulcers* —In one case (1) in which the condition had existed for years there were two or three deep chronic ulcers

3 *Distension of the stomach* —This is often present and in some cases is enormous Especially does it *seem to have* called for comment in those cases in which obstructive symptoms were present but the latter were not necessarily associated

4 *Accidental perforation* —Distension may lead to thinning of the stomach wall *and has enabled a trivial* accident to produce perforation and the extravasation of the copious contents *into the pleural cavity In the case in* which this happened hæmorrhage was found to have taken place from a vessel which opened upon the perforation (1)
differ little from the
circumstance of the
pleura that cavity
and a considerable

lation of the stomach seems to be different *from ulceration in strangulation of the* intestine In the latter it begins on the mucous surface and extends to the outer coats In the case of the stomach the available evidence points to extreme distension producing splits through the peritoneal and muscular coats, perforation being staved off for a time by the integrity of the sodden and rotten mucous membrane (61). Further, ulceration does not appear to have been noted at the seat of constriction, the most common place for it in the intestine.

6. *Strangulation by volvulus of the stomach or by torsion of the small omentum.*—There is one form of strangulation of the stomach met with in diaphragmatic hernia of that organ which presents unusual pathological peculiarities and which has not hitherto received any attention. It may be thought that strangulation of the stomach by volvulus is rather a far-fetched idea, but it undoubtedly does occur and my attention was first directed to it by a case in which the post-mortem appearances were most unusual and their explanation apparently very difficult. Subsequently he met with a case which had occurred at St. Bartholomew's Hospital in which presumably identical appearances had been found, and from a careful consideration of the two cases the conclusion was reached that both owed their peculiarities to twists by which certain vessels in the small omentum were affected and that the engagement of a portion of the stomach in a hernial orifice in the diaphragm was a feature essential to the condition. For permission to include the St. Bartholomew's Hospital case I am greatly indebted to Mr. A. Willett under whose care the patient was admitted and to Mr. James Berry who made the post-mortem examination.

CASE 2. *Diaphragmatic hernia of the stomach; torsion of the small omentum; strangulation; death.*—A female, aged 29 years, was admitted into the Leeds General Infirmary under the care of Dr. Churton on Feb. 19th, 1901. Three months after a confinement and 18 months before admission she began to have dyspeptic symptoms. Later, vomiting after food set in and continued throughout another pregnancy which terminated without difficulty on Dec. 8th, 1900. Shortly afterwards streaks of blood occurred in the vomit and continued when the patient was not under treatment. On Dec. 15th she was poulticed for acute pain under the left shoulder. The patient was a pale and delicate looking woman and when admitted weighed 6 stones 11 pounds as against 8 stones 7 pounds two years before. Nothing abnormal was detected in the lungs. Both sides of the chest moved equally. There was a good entry of air. The percussion note was good and tactile vocal fremitus was normal. The heart's apex was felt in the fifth left interspace two and a quarter inches external to the middle line and the pulse was regular and 84. The bowels were difficult to regulate. Under a milk diet the vomiting ceased. On Feb. 21st she was allowed beef, potatoes, and rice pudding for dinner; indigestion followed and the pain became worse at 7 P.M. She vomited. At 10.30 P.M. she was much worse and collapsed, with cold hands, great pallor, and a very feeble pulse of 120. Pain was felt in the epigastrium, the left hypochondrium, and across the body over the lower ribs. Liver dulness was uncertain. There was no marked abdominal distension but there was some rigidity over the epigastrium. Respirations were increased (27) and the entry of air into the left lower lobe was decidedly diminished. Over the last four or five lower ribs on the left side in the posterior axillary line an extraordinary sound like gas or air blowing into a cavity was heard during expiration. One observer described it as "bubbling." The patient was suspected to be suffering from gastric ulcer and the rapid development of these very acute symptoms was thought to point possibly to perforation. Under this impression I was asked to see the case with Dr. Churton and though the patient's condition was extremely bad it was felt that an operation should be performed. Ether was accordingly administered and transfusion was immediately commenced. The abdomen was opened by a median incision above the umbilicus. The left lobe of the liver descended to within one and a half inches of the umbilicus. The stomach could not be seen. The colon was empty. The spleen and portion of the pancreas were easily brought into the wound. Underneath the liver, where the stomach should have been, there lay a mass of omentum which could not be drawn away. Covered by this and placed deeply near the back of the liver a very tense, globular tumour was felt. It was fixed. On teasing through the omentum it was seen to be the stomach, tightly distended, and of a bluish grey colour, and with several peritoneal lacerations of considerable size. The finger could be passed over a considerable portion of its surface without encountering any impediment. A stomach-tube was passed. The tumour disappeared at once and it was only by the presence of the tube that the whereabouts of the stomach could be detected beneath the omentum. Though there was a momentary improvement in the pulse on the relief of the distension the patient's condition rapidly began to fail and it became obvious that she could not bear the prolongation of an operation in which grave complications were certain. The abdomen was therefore closed. Five pints of saline solution had been injected into the median basilic vein. Death took place two hours later.

Necropsy.—When the body had been opened a large tumour was seen to exist in the right thorax in close contiguity with the pericardium. The tumour was the sac of a diaphragmatic hernia, was tightly distended, and as large as a very big cocoanut. It was surrounded by the lung which had been hollowed out like a cup by the tumour projecting into its base. This cup-shaped depression in the lung was the result of adaptation, not compression. Below the diaphragm and coming from behind the left lobe of the liver, which was tilted forward, was another tumour as large as that in the right thorax and tightly distended. This tumour, composed of the cardiac extremity of the stomach, was bluish in colour, deeply congested, and showed several large peritoneal cracks. The pylorus and first part of the duodenum were found on the right side of the tumour posteriorly and were quite normal in appearance. They could be traced to the diaphragm. The hernia was now reduced. The contents consisted of a small portion of the great omentum and the middle two-fifths of the stomach distended with fluid and gas. The portion that had lain within the sac was normal in colour and appearance. It was marked off from the pyloric portion, which remained in the abdomen, by a pale crease, but evidently there had been no interference with the circulation produced by the constriction of the neck of the sac.

On the other hand, there was a very sharp line of demarcation between the herniated portion and the cardiac extremity which had constituted the tumour in the abdomen. The latter showed marked signs of strangulation. Both surfaces of the fundus presented considerable peritoneal ruptures, which in some instances extended through the musculature and exposed the rotten mucous membrane. One of these perforated notwithstanding the care taken in the examination of the organ. On the internal surface of this portion of the stomach there was a hæmorrhagic erosion in addition to deep congestion and softening of the mucous membrane. The mucous membrane of the herniated portion showed nothing abnormal. The protrusion had taken place through the œsophageal opening and on the right of the gullet. It had passed behind the pericardium and, carrying before it the peritoneum continuous with the anterior surface of the gastro-hepatic omentum, it had received an additional covering from the right pleura. The sac was

Duodenum.

pedunculated and on its mediastinal side it had contracted an adhesion to the lung. Beyond the mobility of the spleen and pancreas no other abnormality of importance was found. (Fig. 7.)

CASE 3. *Diaphragmatic hernia of the stomach; volvulus of the stomach; strangulation; death.*—A man, aged 50 years, was admitted into St. Bartholomew's Hospital on Oct. 19th, 1897, under the care of Mr. Willett, in a state of profound collapse and died on the stretcher as he entered the ward. He had suffered from severe abdominal pain and almost continuous vomiting for four days until relieved by morphine. When admitted he was quite conscious and the abdomen was distended in the upper half and not tender.

Necropsy.—The post-mortem examination was made by Mr. Berry. The left lung was much shrunken and occupied only the upper half of the left pleura. There were no adhesions. Bulging into the left side of the chest and covered by normal pleura was a large nearly globular sac measuring between four and five inches in diameter. It had a broad pedicle at the inner and lower part and was clearly a diaphragmatic hernia. "Abdomen.—The peritoneal cavity contained free gas. The lesser peritoneal cavity was greatly distended and filled with a thin, nearly black, fluid looking like altered blood. This sac formed a huge globular mass occupying most of the upper quadrant of the abdomen. The transverse colon ran across the lower part." "The stomach was remarkably abnormal in shape and position. About one-half of it—the cardiac end—was greatly distended, forming a rounded sac some six inches in diameter. This portion bulged into the lesser peritoneal sac above mentioned At the lower border was a small perforation through which blackish fluid mixed with particles of food was oozing into the peritoneal cavity. A fairly well-marked and evidently old constriction separated this half of the stomach from the pyloric half which lay in the hernial sac. Nothing else but stomach lay in this sac and there was no inflammation, congestion, or other sign of strangulation. There was no fluid in the sac. When the pyloric half was drawn out of the sac the whole stomach was seen to be enormously dilated and the lesser omentum was greatly widened, being seven inches across at its widest part. A constriction at the pylorus marked the lower limit of that part that had been in the sac. The cardiac portion of the stomach was considerably decomposed and it was difficult to say whether the perforation was ante or post mortem. It seemed probable, however, that it had occurred a few hours before death on account of the large quantity of fluid distending the lesser peritoneal sac." "Diaphragm.—The opening in the diaphragm through which the hernia occurred was oval or nearly round and measured about two inches in diameter. It was situated just to the left of the œsophageal opening, the herniated portion of the stomach passing in front of the œsophageal end before entering the hernial sac. (Fig. 8.) The hernial opening appeared to have been congenital and the stomach had evidently been in the habit of passing freely into the sac for a long time. It was easily reduced by pulling and had probably often been spontaneously reduced. There was no sign of old injury to ribs, liver, diaphragm, or any other part." There was also a shrunken gall-bladder containing stones with some old adhesions around. There was no disease of any other abdominal viscus. (*Note.*—I assume that the condition of the cardiac end of the stomach described in these notes was due to strangulation.)

FIG. 8.

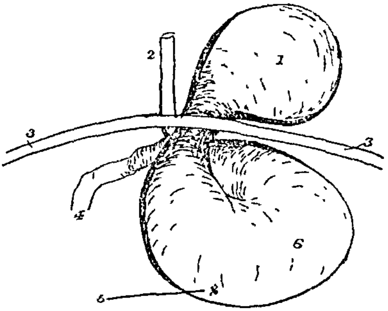

Diagram in connexion with Mr. Willett's case. Volvulus of the stomach. 1, Pyloric half of stomach in hernial sac. 2, Œsophagus. 3, Diaphragm. 4, Duodenum. 5, Perforation of (6) Cardiac end of stomach.

There is one remarkable fact common to these cases that cannot fail to arrest attention—viz., that strangulation affected a part of the stomach which had not entered the hernial sac, whilst the hernial contents themselves were quite normal and uninjured. Indeed, there was no real difficulty experienced at the post-mortem examination in expressing those contents in the first case and in pulling them out in the second. Obviously the conditions were unusual. What is the explanation? The most important factor is torsion of the gastro-hepatic omentum from right to left through an angle of 180°. It only requires a glance at Figs. 7 and 8 to realise that the right-hand portion of the small omentum must be pulled very much out of its natural position and have its relation to the left-hand portion very much altered. As a matter of fact, it is pulled across it at right angles The right-hand border, with the pylorus and duodenum attached, in its course to the aperture in the diaphragm lies superficial to the left-hand portion of the omentum and to the coronary artery and vein. In Mr. Willett's case it passed in front of the cardiac end of the stomach and a true volvulus of the stomach was produced, but *in Dr. Churton's and the writer's case, the hernial orifice* being on the right side of the œsophagus and not on the left as in Mr. Willett's, this crossing of the stomach did not occur, but as will be readily understood the torsion of the omentum would be more pronounced.

Now the reason why only the cardiac portion of the stomach, situated outside the hernial sac, shows the effects of strangulation is because the circulation through the coronary artery and vein is interfered with. These vessels pass underneath the right-hand portion of the omentum and the pyloric portion of the stomach and which constitute a firm solid band of tissues fixed at either end—on one side at its engagement in the hernial orifice and on the other at the attachment of the lesser omentum to the transverse fissure of the liver. The arrangement of the parts is diagrammatically represented in Fig. 9. When in these circumstances, the

mitral cases, nearly half the number, and the importance of rheumatism in their causation stand out prominently. These cases offer a wide field for discussion and if I must content myself with noting only a few points the limitation is made with good reason.

The possessor of a heart lesion may be absolutely unconscious thereof; on the other hand, he may present many symptoms which can usefully be classed as direct and indirect. In the former group we find various subjective sensations—palpitation, dyspnœa, and alterations in the cardiac rhythm; in the latter symptoms which for the most part are attributable to passive congestion of the various organs—lungs, liver, kidney, or brain. Yet another source, embolism, may give rise to symptoms far removed apparently from the primary lesion. It is unnecessary for me to detail the various symptoms but I shall touch upon a few to emphasise the difficulty which we shall often meet in our work.

Let us consider for a moment the subjective sensations that may be present. As you all know, they vary from the merest præcordial discomfort to the agony of angina pectoris. I should say that given a heart lesion the severity of the subjective trouble bears often absolutely no relation to the gravity of the lesion. The fatal case of aortic disease was attended with practically no pain at all. But a still more important point is this, even severe anginal pain causing collapse may occur without there being any actual heart lesion at all. These cases are not seen in my experience in hospital practice, they occur in better-class subjects, often neurotics, who are overworked, either mentally or physically. Close inquiry often elicits a history of irregular feeding and possibly excess in alcohol and tobacco, especially the latter. Rest, careful dieting, and a holiday work wonders. We are all familiar with the abnormal sensations in the chest due to gastro-intestinal disturbance and I have a vivid recollection of a patient in the ward of the late Dr. A. Davidson whose "mediastinal tumour" was removed by a few doses of Gregory's powder. A much more serious difficulty I can illustrate with a case.

CASE 1.—A man, aged 48 years, was sent to me for severe anginal attacks. His medical adviser failed to find any condition to explain them. I in my turn found the heart and vascular system quite healthy. The man was kept under observation and eventually definite evidence of nerve-root implication was obtained and finally the case was cleared up by the appearance of œdema of the left arm. A necropsy showed a malignant growth starting from the upper dorsal vertebræ.

Palpitation is another symptom which may be considered for a moment or two. Perhaps of all heart symptoms it is most often unaccompanied by heart lesions. Anyone conscious of his heart's action may be said to have palpitation; the heart's action may be unaltered or may be irregular. In either case careful attention must be paid to the apparent exciting cause. When due to severe exertion it is a physiological phenomenon, but when it appears with slight exertion some underlying state can usually be detected, such as neurosis, chlorosis, or heart trouble. It may also appear, apart from exertion, after the intake of food or emotional disturbance, and its association with gastric disturbance is well known. By far the most frequent variety is the nervous one, with a weak nervous system, whether inherited or acquired. Palpitation appears under the strain of the body changes at puberty and the menopause, or under physical or mental overwork. Similarly many cases of tea and tobacco palpitation have a nervous basis.

Is nervous palpitation due to sympathetic stimulation or vagus inhibition? In many cases it is impossible to say. In some, however, the associated vascular changes justify the implication of the former. Two cases will illustrate this.

CASE 2.—A young male neurasthenic came to the infirmary suffering from palpitation which I found to be associated with marked pulsation in the vessels, notably the abdominal aorta. This condition has been termed by Dana pulsating neurasthenia.

CASE 3.—In private I saw a young male adult who with severe attacks of palpitation had marked tachycardia and wasting. Three months' rest produced a complete recovery which has been maintained for over three years.

I always teach that the symptoms of chest mischief may be due to lesions of practically any of the thoracic organs, but it is also important to note that chest lesions may give rise to symptoms pointing elsewhere. I may be allowed to give some examples not limited to heart cases. Some years ago I collected a series of cases of pneumonia and found that one-third of the number began with vomiting. I should add that my cases were all adults. A striking case was in my ward last year.

CASE 4.—A man, aged 44 years, was admitted for cough and pain in the chest. He had suffered from a septic finger. The temperature was a septic one, a well-marked leucocytosis was present, and he had signs pointing to effusion in the left chest, deficient movement, absent vocal fremitus, dulness, and feeble bronchial breathing. A needle drew pus but operation found the pleural cavity obliterated. A necropsy a week later revealed a suppurating broncho-pneumonia secondary to an aneurysm pressing upon the left bronchus.

An important case with a direct bearing upon the point I wish to make is the following.

CASE 5.—A woman, aged 46 years, was sent to me with a history of hæmoptysis and some wasting. Her medical adviser had found evidence of consolidation at the apices. I corroborated his finding but discovered further that she had very definite mitral stenosis. No tubercle bacilli were found in the sputum and the further history has shown the lung lesion to be secondary to the heart state.

CASE 6.—Another case I well remember was sent for examination purposes some years ago as one of aortic aneurysm. I am happy to say that our Liverpool students who saw it recognised it as a case of fibroid contracting lung exposing a normal vessel.

A final case in this connexion:

CASE 7.—A woman, aged 27 years, was sent to my colleague, Mr. Rushton Parker, suffering from hæmaturia of recent appearance. No local pelvic cause was found and I was asked to see her. The onset had been attended by sharp pain in the loin and her heart showed definite evidence of mitral stenosis. The hæmaturia was then of embolic origin and disappeared after a week's rest in bed. I might say the patient was not aware of her heart trouble.

---

[1] A paper read before the St. Helens Medical Society.

These are a few striking cases and I have no doubt you could multiply examples from your own experience. The point which I wish to make is then that nothing but a careful physical examination will enable us to disentangle the various chest lesions.

I have often been struck with the method of heart examination practised before inducing anæsthesia. An ear applied directly or with the aid of a stethoscope settles the question of heart soundness in an instant. The matter, however, is not nearly so simple. I suppose the diagnosis is based on the absence of a murmur with a regular rhythm. Now when valvular trouble is present good compensation makes it no bar to anæsthesia and in my earlier days I have given even chloroform in such cases without mishap. On the other hand, a murmur is not sufficient evidence of valvular trouble. It would lead me too far to discuss the whole question but I would remind you that a murmur depends largely upon the speed of the blood current. I am sure that some murmurs heard when the heart is beating very rapidly in excitable subjects are due to this factor alone. The opposite pole will be accepted, I think, by all—viz., that when the heart's action becomes weak murmurs often disappear; this I take it is the probable explanation of the murmur being absent in some cases of mitral stenosis. Again, when a murmur is present the question will often arise, Is it functional or organic? I am accustomed to teach that with no enlargement of the heart downwards or to the left, no accentuation of the pulmonary second sound, with the left ventricle first sound sharply defined, and a systolic murmur loudest at the pulmonary area, then in the presence of anæmia a diagnosis of hæmic murmur is justifiable. However, in some cases a mitral murmur is heard with an accentuated pulmonary second sound and yet we are in doubt. I have just had an interesting case in my ward which will show the difficulty that at times may arise.

CASE 8.—The patient was a girl, aged 19 years. She was anæmic but nutrition was fair. The temperature was 101° F., the respirations were 24, and the pulse was 110. There were some redness, tenderness, and swelling of the right foot. The blood count gave the following result: hæmoglobin, 60 per cent.; red cells, 4,800,000 per cubic millimetre. The apex beat of the heart was in the fifth space, three and a quarter inches from the median line; it was strong, regular, excited; the dulness was within normal limits. The left ventricle first sound was sharp and followed by a systolic murmur, which was not conducted to the axilla. The pulmonary second sound was accentuated.

It is generally accepted that some cases of functional murmur are heard best at the mitral area and if weakness of the muscle ring be accepted as the cause thereof the increase in the pulmonary second sound is readily explained. I decided in this case, although rheumatism was present, that the murmur was functional and I did so because the first sound was so well defined. Within a week the murmur had vanished, so that the diagnosis of relative incompetence was probably correct.

The variety of valvular disease in which murmurs are most often absent is mitral stenosis. The following considerations will guide us in such a case. 1. Evidence of an enlarged right heart: displacement of the apex beat to the left, systolic heaving of the sternum with epigastric pulsation, and extension of cardiac dulness to the right of the sternum. I assume that the lungs have been examined. 2. A diastolic shock in the third left space will give evidence of high tension in the pulmonic circulation. Good observers have stated that a presystolic shock can in some cases be made out in the upper and left part of the cardiac area. I cannot say that I have ever seen it and as it is ascribed to the pulsation of the auricle I do not expect to see it, for I have never made a post-mortem examination in which the left auricle has formed part of the anterior surface of the heart. 3. A presystolic thrill may be present even in the absence of a corresponding murmur. The shock of the closing mitral valve may be detected as an abrupt sensation synchronous with the first sound and by Bard and Cassan is considered to be an absolute sign of mitral stenosis. 4. The left ventricle first sound is often altered in characteristic fashion, becoming hard and sudden—I call it "thudding." At the base the pulmonary second sound becomes markedly accentuated and persistent reduplication of the second sound is a good sign of the lesion. 5. Preceding the first sound at the apex is sometimes heard a dull rumbling sound which may end in a murmur before the first sound becomes audible, the *roulement diastolique* of French writers. The pulse is usually small, regular, and of fair tension. I have a case in my female ward at the time of writing which shows practically all these points. Yet another case:—

CASE 9.—The patient, a female, aged 26 years, was in my ward in January, 1904, with mitral regurgitation. She was readmitted on March 20th with marked loss of compensation, as shown by œdema of the legs, some ascites, right hydrothorax, with orthopnœa and cyanosis. The mitral murmur was absent on admission but became audible in the course of 24 hours after a full dose of digitalis.

It is obvious, then, that th[illegible] examination is necessary to make an [illegible]est cases. The scheme which I adopt for the heart is the following:—1. Inspection of the præcordium. 2. Apex beat: position, extent, strength, character, rhythm, thrills, mobility, abnormal impulses. 3. Heart dulness: change of absolute dulness with full inspiration. 4. Heart sounds: strength, character, relative intensity, rhythm; added sounds. 5. Murmurs: site of greatest intensity, time, lines of conduction, and character. The examination is completed by the investigation of the arterial pulse, venous pulse when present, also liver and capillary pulses, and further assistance is obtained by considering the symptoms and physical signs in the organs secondarily affected. In this way we can usually determine the existence of a heart lesion, but, as Peter has well said, this is merely an artistic satisfaction; a musician could arrive thus far; it takes a sound medical practitioner to make a diagnosis on which prognosis and treatment may be based.

Time will not allow me to enter into the causation of heart disease but the nature of our problem may be illustrated by a case.

CASE 10.—A male, aged 50 years, was admitted into Ward X. for pain in the chest, dyspnœa, and cough. Physical examination detected an enlarged heart; the apex beat which was displaced downwards and to the left, was slightly diffuse, strong, heaving, and regular. There was some dulness in the inner part of the second right intercostal space. The left ventricle first sound was prolonged and muffled; the aortic second sound was musical and accompanied by a short "whiffy" diastolic murmur. The pulse was rather short (collapsing) and the radial artery was greatly thickened and tortuous. The diagnosis of hypertrophy of the left ventricle with a little dilatation, dilatation and atheroma of the aorta, and slight aortic regurgitation was readily made. It was further noted that the urine was of low specific gravity (1007), although deficient in amount, and contained a trace of albumin. The history revealed some renal dropsy, puffiness of the eyelids in the morning and of the ankles at night, of some duration, and, further, that for some years the patient had been obliged to get up at night to micturate. It was evident that the man had chronic renal disease and we had to decide upon the nature of the aortic valvular trouble. Murmurs in renal disease may be hæmic, due to relative incompetence, or the result of actual valvular changes. A diastolic murmur is practically never hæmic in origin, so that we were left with the two latter. It was quite possibly a relative murmur inasmuch as there was evidence of dilatation of the aorta but, so far as I know, there are no physical signs to help us in our decision. The course of the case will often decide and in this case it did so. The patient was kept in bed, his fluid intake was lessened, and in the course of a few days the murmur disappeared; it was therefore a murmur of relative incompetence and not one due to valvulitis.

It would be impossible to notice all forms of heart lesion in which difficulty arises but I should like to mention one other—viz., adherent pericardium. I do so for two reasons—one being its importance in prognosis and the other its bearing upon the diagnosis of mitral stenosis. This latter point was impressed upon my mind a good many years ago by the following case:—

CASE 11.—A young woman, whose age I have forgotten, was in the infirmary with evidence of heart failure, with presystolic thrill and murmur. Ascites was out of proportion to the œdema of the legs. She died and the post-mortem examination revealed general adhesion of the pericardium, with calcification and absolutely no mitral stenosis. The specimen is in the Liverpool University museum. Since that time I have learned to pay less attention to murmurs and more to the other signs of valvular trouble and it has repaid me.

The point which I want to emphasise is this. In a valvular case, especially one of apparent mitral stenosis, always look for the evidence of adherent pericardium and be cautious in affirming the presence of mitral stenosis when such evidence is present. Inflammation of the myocardium and pericardium, pancarditis, is much more frequent than is usually believed. In my opinion the diagnosis of adherent pericardium can only be made when there is thickening in the mediastinal tissue, mere adhesion of the pericardial layers [illegible] of any diagnostic value. It will [illegible] efore, what an important bearing [illegible] l have on prognosis. It is, however, often a difficult matter to speak positively about. The points are as follows: systolic retraction of the intercostal spaces in the region of the apex of the heart; systolic retraction of the left lateral and posterior part of the thoracic wall; diastolic rebound in the lower præcordium; non-alteration of absolute cardiac dulness with respiration; fixity of apex position with alteration in decubitus; diastolic pulsation in the veins of the neck; and pulsus paradoxus. The fixity of the apex site is perhaps the only absolutely unequivocal sign of the condition. The disproportionate amount of ascites is a sign of some importance especially in young subjects, and often perihepatitis is found in association with it, the Zuckerguss Leber of the Germans. My old teacher, Dr. F. T. Roberts, taught me that the apex beat often had a curious character, which he aptly termed embarrassed, and I have found this sign of service.

The character of the cardiac enlargement is often of service in deciding how far any single lesion will suffice in satisfy [illegible] are of [illegible] weak [illegible] increa[illegible] sudden and the heart is already [illegible] failure. Some years ago I saw a case with Mr. W. T. Clegg of Liverpool and within a few days was summoned to a second by him. Both were cases of gall-stone; the first had a sound heart and recovered and the second, who was the subject of mitral disease, died before I reached the patient's house. Potain taught that the tendency to syncope attending gall-stone colic was associated with dilatation of the right heart, and François Franck has shown experimentally that strong stimulation of the bile-duct causes a reflex rise in the pulmonic blood pressure. In this way the difference in the issue of the two cases becomes clear. Another point of value is the general rule that when a cavity of the heart is subjected to strain during its diastole dilatation is the primary result. On the other hand, when the strain occurs during systole then hypertrophy follows. In the first case, if time be allowed hypertrophy follows, and in the second sooner or later dilatation. For example, the high tension of chronic renal disease opposes the systole of the left ventricle and we find typical hypertrophy; in aortic regurgitation the strain meets the ventricle in its diastole and dilatation follows. This, with the secondary hypertrophy, gives us the well-known cor bovinum.

Before considering the question of treatment in heart disease which I shall limit to valvular lesions I must say a word or two on prognosis. There is little to be gained by tabular statements as to the gravity of the various valvular lesions, each case must be gauged on its own merits. Aortic regurgitation is usually regarded with great dread as a cause of sudden death. In my cases I have only met this accident twice, and as one patient had septic endocarditis I should say, perhaps, only once. In this case, that of a young woman, aged 29 years, no necropsy was allowed and I cannot say whether any other lesion was present. I mention this because in another case of sudden death in aortic regurgitation in which as pathologist to the infirmary I made the necropsy I found that the cause of death was the rupture of an aneurysm of the intra-pericardiac aorta into the pericardial sac. Myocardial lesions, too, may cause sudden death.

The nature of the lesion must be determined in order to make the diagnosis, the history considered with care, and the examination of the patient may give the clue. I have a patient in my ward as I write with aortic regurgitation in whom an attack of pneumonia seems to have been the exciting cause. Post-pneumonic valvulitis is said to be usually aortic in site. I might mention that, according to French writers—Troisier, Teissier, and others—cases of mitral stenosis occur in which the tuberculous toxin is the exciting cause. In only one of my 13 cases does this seem the probable sequence of affairs.

The degree of the lesion is the second point. In regurgitant lesions the presence or absence of the corresponding sound will help but the main guide is the alteration in size of the heart. It cannot be too carefully borne in mind that loudness of murmur is no guide to degree of lesion.

The compensatory changes come next. When we find them adequate to the new condition the bearing upon prognosis is obvious, but when they have failed the problem is a little more difficult. We have now to consider whether compensation has failed on account of some special strain or because the reserve force of the myocardium is finally exhausted. In some cases only the result of treatment enables us to decide this question.

Finally, the general history and condition of the patient and his hereditary tendencies will give assistance in settling, so far as human skill can do so, the outlook so important to the patient. I need hardly say what importance the social status bears in regard to this matter of prognosis.

To turn to the second division of my subject I find the following subdivision of cases of service in outlining the treatment: (1) compensation practically equal to the lesion; (2) compensation only equal to the lesion when the patient is at rest; and (3) compensation unequal to the lesion.

(1) Should the patient in the first subdivision be informed of his trouble? I believe myself that this is always a wise procedure, otherwise it is difficult to get the necessary mode of life carried on. In general terms we must warn him against excess of all kinds, mental as well as physical. It is not necessary to forbid exercise in moderation; cycling and so on are permissible as exercise but not in competition. If cycling be indulged in care must be taken not to struggle against head winds or up-hill. Moderation in the use of alcohol and tobacco must be enjoined, abstinence even being advisable General dietetic and hygienic measures should be borne in mind. I might add that even in this stage in mitral stenosis there is the risk of hæmoptysis or embolism. The treatment I have found most useful in hæmoptysis is a free saline purge, with a dose of opium. Are such lives insurable? I suppose most offices would reject aortic cases but would accept mitral cases with an addition to the premium. For my own part I should not advise acceptance, but when such a case comes for report I make it a rule to give a full report on the lines I have sketched and leave it to the office to decide. My reason for refusal is the impossibility of foreseeing accidents, such as infection.

If the patient is a female, what should be our advice, if asked, as regards marriage? The less common form, aortic trouble, is a bar to matrimony. Well-compensated mitral regurgitation cases often pass through pregnancy without trouble; in stenosis cases, although the same favourable course is possible, yet at times grave symptoms arise and notably attacks of tachycardia or acute œdema of the lungs. If pregnancy occurs in a case of mitral stenosis the patient should be kept under observation and the slightest sign of distress should be actively treated. Limited diet, free action of the bowels, with possibly bleeding in the more threatening cases, will sometimes ward off the necessity for terminating the pregnancy. Our advice should certainly be against marriage.

(2) In the second subdivision we find cases in which palpitation, præcordial pain, and dyspnœa are manifest on exertion, and in a more advanced degree some passive congestion and its results in the kidney and liver. In aortic cases throbbing in the neck vessels, headache, and giddiness may be troublesome. Absolutely the best treatment is a week in bed with limitation of fluid and regulation of the diet and moderate purgation. A belladonna plaster often gives relief, whether it acts medicinally or psychically matters little. In aortic cases I have found bromide and iron give relief. General tonics, iron, strychnine, and the like, with perhaps small doses (from two to three minims) of tincture of digitalis where rest cannot be taken will help to put our case into subdivision (1) It is of great importance to determine the nature of the valvular lesion: Is it associated with vascular and renal disease or is it purely cardiac? The tension of the pulse and the state of the artery are valuable guides to treatment; when the former is high and the latter shows signs of disease a rigid milk diet coupled with diuretics

acting on the kidney, such as the xanthin derivatives and the use of some mineral water, will help to lower vascular tension by eliminating toxins.

(3) The case of valvular disease, whether aortic or mitral, which reaches hospital suffering from the signs and symptoms of failing heart needs little description. The heart chair to maintain the trunk upright is often necessary. I need not dilate on the necessity for care in feeding but would simply say that limitation of fluid is often of great service. The bowels may be gently acted upon. Sleeplessness is often a troublesome symptom in mitral cases attended with marked mental depression. In aortic cases excitement and even maniacal attacks may be present; I have seen one case of violent mania in aortic regurgitation. The modern hypnotics—trional or sulphonal and paraldehyde —sometimes suffice but opium is our sheet anchor. I have never forgotten a case of heart disease in a young subject which was admitted to the infirmary when I was a house physician. Apparently all our efforts had proved futile but opium before food was ordered in the form of liquor opii sedativus and liquor pepticus after food. The girl forthwith began to mend and eventually was able to leave the hospital in very fair condition. I have seen good service rendered by the old pill of squill, digitalis, and mercury when the engorgement of the stomach and liver has been marked, and blue pill is the well-spoken-of remedy of many sound practitioners. Should we use digitalis in aortic cases? The answer to this is not quite simple. When we find thickened arteries and possibly some increase of tension in the radial pulse, placing the case in what Huchard and his pupils would call the cardio-vascular class, there is no doubt that the best line of treatment is to limit fluid intake, open the bowels, and give renal diuretics. If direct cardiac stimulants are used I prefer strophanthus. As common practice in these cases I give strophanthus through the day with a dose of agurin night and morning. Even in these cases, however, when the pulse tension is low, digitalis is demanded, and I have no hesitation in giving it to an aortic case when the mitral valve has yielded. Trousseau's diuretic wine is a good remedy in similar cases. When digitalis cannot be taken by the mouth the hypodermic use of digitalin will often start the case on the way to convalescence. I need hardly say that in some cases œdematous fluid will have to be removed by instrumental measures; this especially applies to the accumulations in the serous cavities. Dyspnœa is often improved by the use of atropine and strychnine hypodermically. The sinking sensation so often complained of by cardiac patients in the later stages can be alleviated by the exhibition of solid opium or neat brandy.

Liverpool.

THE RELATION OF INEBRIETY TO INSANITY AND ITS TREATMENT.

BY ROBERT JONES, M.D. LOND., M.R.C.P. LOND
RESIDENT PHYSICIAN TO THE LONDON COUNTY ASYLUM, CLAYBURY

THERE are several groups of alcohols in which the physiologist and the physician are interested and these vary from the monovalent alcohols, such as ethylic, propylic, and amylic alcohol through cholesterine, glycerine, and cellulose to the pentavalent phenols and other aromatic compounds. Speaking generally, from their action upon man only the monovalent group concern the subject of our consideration. The effect of alcohol upon living protoplasm has been carefully studied by competent workers and the literature of the subject is full and extensive. Alcohol stops the germination of spores and grains and when the proportion of alcohol exceeds 20 per cent. in the material undergoing alcoholic fermentation further action is stopped, so that this quantity of alcohol becomes lethal to its own development and all further fermentation is arrested. Alcohol is a dys-osmotic and when ingested it passes with difficulty through the living cellular membrane of the capillaries into the tissues. It causes a reaction on the part of these cells which in consequence proliferate and the capillary walls thicken, in this way not only depriving the special organs of their necessary nutriment but also retarding the excretion of waste material which thus accumulates in the tissues and interferes with their healthy and normal functions. It is this accumulation of effete material which has given rise to the view that poisoning from alcohol is not a direct toxæmia but an indirect one from the production and the accumulation of leucomaines. It is further known that alcohol is a strong dehydrating agent, and as dehydration is as hurtful to protoplasm as superhydration, and as a fixed amount of water is therefore necessary to healthy protoplasm, indeed more necessary for protoplasm than is oxygen—for oxygen cannot reinvigorate dry protoplasm—this dehydrating action of alcohol upon protoplasm is highly injurious. The effect of alcohol upon protoplasm is to paralyse irritability, diminish sensibility and contractility, and when sufficiently concentrated to suspend the action of all ferments. The experiments of Féré upon incubating eggs also show the evil influence of alcohol upon the metabolic, the motile, and the reproductive functions of animal cells.

The causes of inebriety.—It has often been asked, "Why do men drink?" There are probably different reasons among different classes in the social scale. The rich drink for artistic and æsthetic reasons—a good meal is made a better meal. The poor drink in order to get a good meal. It is believed that the stimulation—mistaken for nutrition—is more easily obtained from drink than from a meal, which is more expensive, more difficult to select, to prepare, to cook, and to serve. The poor also get light, warmth, comfort, and society in the public-house. Poverty itself is a cause of drink and drink helps them to forget their human misery, but I believe drink is more often the cause than the effect of poverty. It calms physical and moral pain and the pleasure obtained becomes a customary want. The rapid increase in the volume of wealth and the profits of trade make it easier for the mass to obtain alcohol and there is in many instances a temptation (through facility of access to it) from the number of public-houses. Lastly, there is no doubt that the hurry, the artificial desires, and the quest of pleasure characteristic of civilisation favour drinking habits in both men and women.

Physiological effects.—Alcohol brings about marked degenerative changes in the nervous, muscular, and glandular tissues. Its action is a structural one, and change of structure implies altered function. We find these altered functions manifested in commencing intoxication, when the ideas flow with unaccustomed facility, words are uttered more freely, and language becomes more expansive and confiding, cares vanish, everything seems more full of attraction, and the world seems better. There is a sense of *bien-être*, the eye is kindled, and the visage and the physiognomy are illumined; but this picture soon falls into shadow, for the ideas soon become dissociated, the intellect pales, and words become a vertiginous whorl. The memory becomes affected, the gaiety and the optimism of the previous stage are replaced by sadness, tears, and a querulous or dour disposition; all the senses are overshadowed and the mind ere long becomes a listless chaos without order or purpose. The higher psychic faculties disappear in the order of their importance, there is loss of prevision and judgment, there is failure in the concentrating or focussing power of the mind, and the memory and the attention are both enfeebled. Alcohol attacks first the hierarchy of the organic functions, those which are in the front rank, and they are affected in the inverse order of their development, those last developed being the first to surrender; inhibition or self-restraint—the reserve characteristic of the self-respect of higher man—being first withdrawn. The initial flush of excitement referred to above is readily explained upon physiological grounds by the effect that alcohol exerts upon the capillaries which undergo initial dilatation and subsequent paralysis. The intellectual exaltation noticed has no bearing or relation to genius; it is merely a suspension of the highest faculties which permits the next highest to rise into prominence; it sets free the shackles and removes the veil from a less highly evolved mental plane, and free play is given to the uncontrolled feelings. The effect of alcohol is to stimulate the desires whilst diminishing the power to gratify them. It creates a false feeling of strength which when taxed is not sustained, and alcohol is dissipative rather than conservative of energy. The extension of the effect of alcohol to the motor areas is characteristic and the final stage of complete muscular paralysis is well known as occurring in the wake of unsteadiness, the gait of the inebriate being too familiar to need description. Coexisting with the mental changes are those material ones in the nervous system, the muscular and the glandular tissues Alcohol in large doses has been proved to cause changes in the pyramidal cells of the brain It destroys the fine processes of the cells which swell from degenerative changes, their outline is altered and the nucleus is displaced or extruded Fatty changes are produced in the voluntary and the involuntary muscle fibres and also in the different gland cells which in consequence alter the metabolism of the organism An increase also takes place in the amount of fibrous or cicatricial tissue both in the blood vessels and in the various secreting glands, so that malnutrition is induced and a lowered resistance to disease occurs which reduces vigour and diminishes vitality As to the increase of fat in the body, the statement is not maintained that alcohol itself is consumed to supply the energy which is normally obtained from tissue changes [illegible] oxidation" over the body [illegible] the building up process [illegible] noglobin of the red blood corpuscles which takes up and parts with oxygen less readily than normal hæmoglobin The accumulation of fat is due to a general diminution in the metabolism of the body and to an accumulation of waste matter which should be excreted This accumulation of fat is in part an active degeneration as well as an infiltration and it can be proved to be at the exp [illegible] measured by th[illegible] infiltration and [illegible] of acute alcoholic poisoning

Mental effects —The mental effects of alcohol differ as to whether *they are induced by one large dose, as occurs in* alcoholic poisoning or in ordinary drunkenness, or whether they are the result of long chronic drinking even when this *is done in what is described as "moderation" It is a* curious fact, but one well known and appreciated, that the mental symptoms of chronic excessive alcoholism may and sometimes do result from long continued moderate drinking, more especially if the person is overtaken by a serious illness or a severe mental shock also if the drink be spirits The tendency to the development of illusions, upon which are based delusions of a persecutory nature, is very common in persons who drink alcohol to excess, indeed it is not too much to say that persons who become insane and whose symptoms present visual illusions or delusions based upon them, or whose delusions are grandiose, boastful, and vain glorious, or relate to sexual perversions, such as marital infidelity, or are suspicious, distrustful, and persecutory in their character, are almost invariably directly or indirectly caused by alcohol It is almost without exception that when delusions are present as the result of excessive alcohol they are of a malignantly fearful and persecutory character These facts supply a reason for the classification of alcoholic insanity as hallucinatory or delusional Both varieties tend to terminate in dementia which indeed may be the only form the *patient* becoming dull, weak minded, and listless, leading a purely vegetative and automatic life from the onset

Much confusion has resulted from the careless use of terms in dealing with the effects of alcohol Alcoholic insanity is often used as a generic term and is simply defined to be a mental perversion for which alcohol is the prime cause It is often difficult to separate those cases which are *mad* from those who are '*bad* as due to the same cause Both these forms may be seen in prisons reformatories as well as in asylums The forms of mental disorder resulting from alcohol are therefore (*a*) gross dementia, (*b*) maniacal, unrestrained excitement due to hallucinations, or (*c*) permanent delusional states It is often not the quantity imbibed but the susceptibility of the brain and nervous system through inherited or other vice which determines whether a given case shall be considered a lunatic, an inebriate or a chronic drunkard It is well to avoid a definition of insanity but the Inebriates Act of 1879 lays down a legal definition for the inebriate or the chronic drunkard and it is as follows "Any person who is by reason of habitual intemperate drinking of intoxicating liquor *at times* dangerous to himself or herself or to others or incapable of managing himself or herself and his or her affairs" The Secretary of State is advised that intoxicating liquor "may include liquors other than alcohol if their habitual intemperate use brings the consumer into the condition of an 'habitual drunkard A distinction has also been drawn between "drunkenness" and "chronic alcoholism" The latter term is used by the Registrar General in his statistics of mortality, whereas the former is used in furnishing statistics of crime and for police-court purposes There may be considerable chronic alcoholism either among a group of persons or in individuals such as licensed victuallers, barmen, brewers, labourers, and those in general employment by the trade, or among a special class such as commercial travellers, and yet very little chronic drunkenness The vulnerability or the *susceptibility of the various organs is a deciding factor in this classification*

As to insanity in relation to crime, the statistics of medical officers of prisons throw much light upon their close connexion At Aylesbury and Warwick, the two State reformatories, most of those under detention are inherently mentally defective They are sent there in the first instance after an attempt has been made and failed to make them amenable to discipline They are habitually sullen or unreliably excitable and they vary in their conduct from one hour to another They are suspicious and ready to take offence when none was intended At the same time they are free from hallucinations or delusions, their special features being a low intellectual capacity and their inability to follow a train of reasoning or to behave reasonably in daily life They are creatures of impulse and are not amenable to method and order The relation of crime to insanity is demonstrated by the fact that in 64 per cent of the women there was a history of insanity and that 25 per cent of the males who left Warwick and 33 per cent of the females who left Aylesbury were transferred to asylums for the insane

Of all the special symptoms characteristic of forms of alcoholic insanity the condition termed "paramnesia" is the most indicative This is a failure of memory for recent events, an impairment of that special adhesive quality of nerve cells by which the brain is able to retain the images of *past sensations* and in consequence of which there is a marked loss of the power of associating ideas The person is lost and confused, he often brings the long past into the present, he is busy with previous plans, makes imaginary journeys, and has just seen old companions or acquaintances It is this feature in drink cases, this forgetfulness and confusion, which makes men *and women* (*especially the latter*) appear so inclined to distort the truth and to appear to be given to somewhat deliberate and shamefaced lying They are unable to retain *impressions of their own state*ment and those of others and they are incapable of concentrating and fixing their attention upon passing events It is this failure of memory which causes self-contradiction There are also in these cases a busy delirious restlessness and a mental wandering, causing a loss of "orientation," as it has been called, the patient being confused as to time and place Another peculiarity of chronic drinkers is the impulsiveness of all their reactions when excited, often their reaction to sensory, visual, and auditory stimuli is retarded but when they do react they are impetuous and essentially spasmodic and convulsive in character Patients of this class are almost always irritable, sudden, and violent, their temper is unrestrained, and licence in speech and action often becomes apparent in their conduct In one particular class of chronic drinker the moral nature is much perverted, the will power or the inhibition is weakened, but there still remains the knowledge of right and wrong and under a sufficiently powerful stimulus there is power to abstain from [illegible] ve no influence and an [illegible] The conduct, although [illegible] reasonable except upon [illegible] g for which exercises a [illegible] idual, who is now called [illegible] an inebriate Inebriety is of two kinds, one characterised by intermittence [illegible] the constant [illegible] quently in y[illegible] of age When the vice is [illegible] occurs about the period of menstruation The periodic drinkers are generally of unstable parentage and come from a faulty stock affected with some neurosis and evidenced by a history in the ancestors of either drink epilepsy, insanity, or neuralgia After an outbreak of drinking the victims either become exceedingly despondent and suicidal or they may become violent and frenzied from delirium tremens which occurs mostly in this class These conditions pass off after a time to be again repeated but in the intervals of drinking they are agreeable and reasonable and are heartily sick of their own loss of *self control They are* penitent and they promise amendment, indeed, they may loathe the very sight and smell of drink. In these intervals they probably fulfil their natural obligations to those dependent upon them and to society. In these cases also large quantities of alcohol may be imbibed during the drink period without any of the natural physiological effects such as drunkenness or motor paralysis usually seen in the ordinary drunkard. The so-called constant drinkers, on the other hand, are persons usually in later life, and it is these who, before the Act which came into force on Jan. 1st, 1903, disgraced our streets and public places and contaminated our youth. These are morally and intellectually depraved persons who are unfit to associate with decent human beings. They are a reproach to their friends and a by-word of opprobrium and contempt to their neighbours. No amount of persuasion in regard to the evil effects of drink appears to have any influence in preventing persons in either of these two classes from drinking and no argument as to their deadly course is of any avail. They must have their drink even if it pauperises them or makes them the associates of low persons and criminals or even if their families are ruined by it. The pleasure to themselves has become a customary want and must be gratified.

Motor symptoms.—Alcohol induces epilepsy, especially in those who have suffered head injuries, and I have known several cases in which, when the alcohol is stopped, the fits have ceased, reappearing when further indulgence occurs. All drinkers become subject to sensori-motor disturbances and tremors, the lips, the hands, the voice, and the parts most subject to stress being the first affected. It is among the skilled craftsmen whose evolutionised movements do high-class manual work that alcohol plays a havoc and the distress which falls upon those dependent upon these is too well known to need discussion here.

Sensory symptoms.—Owing to an affection of this territory of the nervous system cramps and loss of sensation in the extremities—and most often the legs—are frequent symptoms of alcoholic indulgence. Visceral and other hallucinations are common and complaints as to electricity and machines are quite frequent. The lesions in this form are in the main peripheral, they are also mostly bilateral and tend to be centripetal. As to the pathological cause of disturbed sensation, it may be the direct anæsthetic effects of alcohol acting peripherally upon the terminations of the sensory or motor nerves; it may also be a direct effect upon the cortical neurons which are the central representatives of these projections.

Susceptibility.—We are unable to foretell definitely the particular group of neurons likely to suffer in any special case of alcoholic indulgence, neither can we give the progress of the symptoms when a group of neurons has been attacked. This fact demonstrates the existence of a *locus resistentiæ minoris* for each individual. We know that some persons break down from arterio-sclerosis, thrombosis, hæmorrhage, and softening, others from a fibrous infiltration of the glandular structures, and others again from mental or nervous lesions. We know, for example, that syphilis in the parents may be evidenced in one or more of the immediate descendants whilst the other children escape altogether. In many cases all the children may escape stigmata. In some we find locomotor ataxia in the father developing general paralysis in the son and *vice versâ*. What it is that constitutes the immunity in the one case and the susceptibility in the other we do not know. We do know, however, that alcohol has an affinity for the highest developed functions—both mental and physical—and that stress of a particular organ renders that organ more vulnerable and more liable to surrender. For instance, alcoholic peripheral neuritis has been known to occur in the right arm of a barmaid, whilst the lower extremities have escaped entirely. This susceptibility or the personal equation of the individual is a dominant factor in the incidence of disease other than the result of alcohol.

General results of alcohol.—In chronic alcoholism the effects produced possibly bear more relation than is usually accepted to the form of alcoholic mixture taken and the deleterious effects of spirits are combined with those from a category of mixed poisons; the amylic alcohols in crude whisky—most of which is now prepared, not from malted barley, but from molasses, rice, or maize and which is served in a raw state—probably have a more injurious and a different effect from that of the lighter wines. Such a poison as absinthe, mixed and served with raw spirit, must have a hurtful influence of its own in addition to that from the manufactured and inferior spirit. Richet states that the more volatile the spirit the more marked are the anæsthetic effects of alcohol; the less volatile it is the more marked are the convulsive effects; and that the more soluble in water the alcohol may be the more marked are the inebriating effects. I should like to hear this question of the influence of different forms of alcohol upon the individual further discussed. I am of opinion that among the poorer classes, whose beverage is mostly beer, there is considerable malnutrition found as the result of beer-drinking which induces gastric catarrh. The beer undergoes further fermentation when ingested, the lower forms of bacteria develop and multiply, and the formation of foul gas causes dilatation of the stomach and dyspepsia; this gastric and intestinal irritation, which is more marked than the glandular cirrhosis caused by spirit-drinking, often gives rise to wasting and diarrhœa, with a lowered vitality.

The evil effects of alcohol may readily be seen in the subjects of surgical operations who are beer-drinkers. Their wounds take long to heal and they are subject to many unfavourable complications. The mental defects in beer-drinkers are those of general impairment and dulness more akin to dementia than the perversion, the suspicion, the cunning, and the delusions so commonly found in spirit-drinkers. There is no doubt that one of the chief results of alcohol is a tendency to fatty degeneration and to diseases such as pneumonia and tubercle, to skin eruptions of various kinds, to laryngitis, atheroma, motor and sensory disturbances, and also to the various neuroses and crime. It is a significant fact that during the ten years of which I have had experience of the London County Asylum, at Claybury out of a total of nearly 10,000 persons admitted over 22 per cent. of the men and 13 per cent. of the women owe their insanity directly or indirectly to the effects of drink. That alcohol is a poison to the whole animal series is without doubt and that it shortens life is strongly evidenced by the careful statistics of life insurance societies.

Heredity.—There can be no possible doubt, indeed I may say there is general agreement as to the opinion, that alcoholic excess devitalises the individual, both directly and by the influence of a vitiated environment. How far this is transmitted to the descendants is a very vexed question. That parental intemperance is a large factor in the deterioration of the offspring, both mentally and physically, is the opinion of many experts. Whether it is the predominant factor in any definite case is uncertain, for intemperance may be the result of an insane heredity; in such a case it is possible that insanity or some allied neurosis may be the chief cause of the deterioration. Heredity is as characteristic of alcoholism as it is of any other form of moral insanity. It occurs in about 33 per cent. of all cases of alcoholic insanity. Various kinds of neuroses may be found in the family history of almost every inebriate and this condition tends to predispose to inebriety in those who taste and partake of alcohol. Further, I am able to affirm from an extensive experience in a large asylum that the offspring of the drunkard is often a degenerate and a psychopath—a class which is most susceptible to the influence of alcohol. They are more liable to suffer also from delirium tremens and violent mania after taking alcohol, even after a single debauch, than the drunkard without heredity who, on the other hand, suffers more often from cirrhosis of the liver and kidneys and is sent to the hospital for treatment, whereas the psychopath or neuropath with an insane heredity is sent to an asylum. I believe in the transmission of acquired characters but the deductions of morphology, laboratory experiments, and microscopical observations are against this belief. It has been long pointed out[1] in the vegetable kingdom that an alteration in the environment of plants can bring about variations and when the cultivator repeats the conditions which cause these variations the latter become fixed and are inherited. Precisely in the same way does the inductive evidence from observation and experiment afford us knowledge as to the animal kingdom; the alcoholic environment is capable of bringing about a modification in the offspring as is seen in the attenuated neurotic children of many drunken parents. As having a special bearing upon this aspect of the transmission of acquired characters may be mentioned some unpublished experiments of Dr. G. A. Watson who injected guinea-pigs with ricin and created an acquired immunity to 1000 lethal doses in the immediate offspring. In the face of such results it is not too much to be quite certain that alcohol in the parent affects the offspring. Furthermore, in the vegetable kingdom we know that Alpine plants have a certain "facies," they are stunted in size but brilliant in bloom, and moist tropical flora,

---

[1] Henslow: Royal Horticultural Society, 1904.

together with the flora of the dry desert, have each their "facies." Moreover, dicotyledonous plants have finely dissected leaves when growing under water. All these facts tend to show the influence of the environment which is acquired and transmitted because the seeds transmit the characters, the plants all coming true by the seed. It was an axiom of a celebrated French botanist that everything tends to become hereditary. A few generations encourage acquired traits in man, as may be seen in the appearance and bodily conformation of certain country folk, and nature tends to fix these. We can often tell the town-dwellers and their children from characters induced by their environment and partly from the transmission of these acquired characters through heredity. It is not too much to say that there is a definite response on the part of living protoplasm to changes in the environment and these changes become adapted to the new conditions of the organism and tend to become acquired. We can control inherited vice by a change in the environment and if the new and favourable environment is maintained and the surroundings are healthy we are able to remove some of the most fertile causes of drink. In sanitation and morality, plenty of pure water, fresh air, radiant light and sunshine, rational pleasures, education as to the value of good food, how to select it, and how to cook it, we have the best antidotes to drinking tendencies. This influence of education, the impressions given by social usage, increased facilities for healthy physical exercise and recreation, and the controlling factor of public opinion as to the effects of alcohol serve *as the best auxiliaries to temperance*. Such means are beneficial to self-respect and tend to sobriety. It is only with a healthy environment that we can sustain the organism in full vigorous health and supply the greatest resistance to temptation.

Treatment.—With regard *to inebriety the treatment* resolves itself into the general treatment of drunkenness and that of the individual. As to the latter it is either in their own homes or in retreats. In both cases it is certain, in my mind, that alcohol should be cut off completely and in the great majority of cases, indeed with but few exceptions, the total and sudden deprivation of alcohol is beneficial. In the few exceptions collapse results from sudden withdrawal of stimulants and this needs careful watching, for in cases complicated with insanity pneumonia is not an uncommon complication. This pneumonia fails to undergo resolution and it ends in phthisis with death probably within the year. Sleep and nourishment form the keynote of treatment; sleep is best obtained by gentle outdoor exercise, failing this by bromides—but not by morphine, as the latter may initiate a new craving. The great motor restlessness so often seen in alcoholic cases and caused by painful visual and aural hallucinations is best controlled by hyoscine in doses of from $\frac{1}{120}$th to $\frac{1}{50}$th of a grain administered hypodermically. Sulphonal and trional (20 grains twice or three times a day) are also useful but they increase the muscular incoördination and as the solubility of these drugs is limited they may disturb digestion and give rise to gastro-enteric catarrh. When the pulse is weak and in the case of elderly persons, paraldehyde in drachm doses is a safe sedative stimulant. It is necessary to watch for retention of urine when patients are under the influence of sedatives and it is also important to notice twitching of the muscles which may indicate uræmia, although *convulsions* may be due to causes other than alcohol, such as diabetes or epilepsy or cerebral hæmorrhage. As to feeding, simple, easily assimilable food—peptonised if necessary and a little at a time—should be administered. The general disturbance of the digestive system, marked by loss of appetite, sickness, or vomiting, often tends to make the taking of food repulsive. In these circumstances ice, effervescing mixtures, salines, bismuth, or lime-water may be useful. The bowels should be carefully attended to and saline aperients taken freely to correct the dyspepsia and improve the appetite, which can often be stimulated by nux [illegible] or strychnine and bitter tonics [illegible] attention must be given to [illegible] of bed-sores, for the tissues of alcoholic persons are peculiarly unresistive and bed-sores once formed are most difficult to heal. For the cure of inebriety I do not know that there is any drug that can be relied upon and the secrecy of the various cures indicates their futility.

The following case under my care is typical of a great number of persons enslaved by alcohol and brought into retreats. A married woman, aged 21 years, left much to herself as her husband was often engaged in the evenings made undesirable friends who led her into drinking habits. Her father and brother died from alcoholism. Having become a victim she was taken (1) to a private home where she remained for six months and where she paid £60 and extras. She left (with her husband) as cured, but within a week relapsed, underwent (2) a special "cure" lasting a month, and this for four months in succession, each time with a private nurse, for which cure her husband paid 20 guineas per month in addition to payments for board, rooms, &c. Following this seven months afterwards came (3) a "cure," in the course of which she was twice inoculated in the left arm; she remained under this treatment for six weeks and paid 40 guineas. No improvement occurred, in fact she became worse, and two years afterwards matters were so bad that she was separated from her husband. In less than six months she was persuaded to enter (4) another retreat where she remained four months. Two days after she left she relapsed and was taken to (5) another home, where she remained two months, and upon leaving again immediately relapsed and was admitted into another home (6), where she remained from six to seven months, and underwent the treatment recommended in the previous home, taking "some medicine" every hour for 28 days. At the end of that time she wrote a testimonial that she had lost the craving and that her nerves were better. She soon relapsed and was then transferred to another home (7) where she remained four months. Two days after she left there she became absolutely drunk again and was brought to Claybury Asylum *for attempted suicide* where she has remained a year. She is about to be discharged as there are at present no indications of suicidal insanity.

I would here enter a protest against the gratuitous puffing of quacks and their remedies by the clergy, some of whom appear almost to ply a trade in these vaunted nostrums. What would be said of medical men who publicly opposed the teaching of clergy holding advanced theological doctrines or who pointed out what they considered to be false teaching or excessive ritual in the ranks of the ecclesiastical hierarchy?

The general treatment of drunkenness has become a question for the statesman, the reformer, and the philanthropist. The public, seeing the evil of excessive indulgence, has taken the matter into its own hands and has insisted upon special legislation to deal with drink. It acknowledges that excessive facilities mean excessive drinking and areas of congested population with a large supply of public-houses are also areas of excessive disease and mortality from alcohol. Measures which control the sale of drink assist sobriety. This is not only the testimony of the police but also of others who are responsible for the regulation of disorder and the scope of the present Licensing Bill is upon this basis. In so far as the treatment of inebriety by restraint is concerned the law at present permits *of detention in* (1) *retreats, or* (2) reformatories, the essence of the treatment being to cut off the patient completely from alcohol and the recognition of the fact that inebriety *is a vice and that the victims* are not insane. The Inebriates Act of 1879 allowed a chronic drunkard voluntarily to enter a retreat and to segregate himself from the rest of society with a view of reforming his character by improving his will-power. The Inebriates Act of 1898 *compulsorily* ordered his detention, and a "retreat" into which admission is enforced is no longer called a "retreat" but a "reformatory."

Retreats are for inebriates; *reformatories* are for law-breakers as well as inebriates. Retreats are for the treatment of private drunkenness in private life—i.e., for those persons who bring misery and ruin upon themselves and their families. A retreat is an institution conducted for the control and treatment of a certain class of inebriates and may be conducted by one or many persons under a licence from a county or borough council. Persons who enter retreats go there voluntarily; *they actually ask for detention* which must not be for over two years and they submit to restraint. Two documents are necessary: (1) a request for reception, or retention after reception, or for readmission—if within five years of a previous residence—signed before a magistrate; and (2) a statutory declaration, in view of admission, signed by two friends, also before a magistrate (or a commissioner of oaths). Persons thus received are "patients under the Act" and 259 "patients under [illegible] discharged, and 199 [illegible] An inebriate may also [illegible] magistrate's attestation, there being only the applicant's request, but in this case he cannot be detained against his will, even if he has promised to stay for any definite period, and if he leaves he only forfeits his payment if he has not stayed his full time. Such patients are described as "private patients" and 293 such patients were admitted into the 21 retreats existing in 1902, whereas 283 were discharged and 216 remained under treatment. It will thus be seen that about one-half of the total 552 (247 males and 305 females) persons admitted under care into retreats was of the voluntary, temporary, or "private patient" class. A patient received into a retreat may have "leave of absence" or he may be discharged before the period of detention expires if the licensee recommends and a magistrate consents and a notice of intention to discharge is sent to the Secretary of State. It may be pointed out that in some countries (France, Germany, and Austria) "guardians" can be appointed to look after the property of the inebriate and to compel his detention in a retreat, a power similar to that given to magistrates by the Act of 1898, but upon the question of legal care of inebriates, as also upon other matters, reference must be made to the special report of Dr. R. W. Branthwaite to the Home Office.

Reformatories are of two kinds—viz., (1) State reformatories, of which two exist—one for females at Aylesbury and one for males at Warwick—established (*a*) for the 10 to 15 per cent. of more refractory cases in other reformatories and (*b*) for those committed from the assizes or sessions and not from police courts; and (2) certified reformatories for criminals and police-court cases, called "police-court recidivists." These reformatories, of which there are now eight with 624 beds, are of two kinds (*a*) philanthropic and (*b*) rate-aided from local authorities which are established for impoverished and destitute persons. At the end of 1902, four years after these were first established, 714 persons had been admitted and there were 419 under detention at the end of the year 1902, 278 (46 males and 232 females) having been admitted during the year. At first there were more males than females; at the end of four years, however, the males remain the same but the women have doubled. Two kinds of cases are sent to reformatories: 1. Persons convicted of habitual drunkenness and a crime punishable by imprisonment or penal servitude and called criminal inebriates. These are sent to State reformatories but they may be sent to certified reformatories, the Secretary of State having power to transfer them subsequently to State reformatories; 46 were so sent during 1902. 2. Persons who had committed a scheduled offence (mostly different kinds of intoxication) and against whom there had been three previous convictions for drunkenness within the year. These are sent to certified reformatories; 232 were so sent during 1902. In June, 1903, there were no fewer than 495 persons of the worst possible class and character detained in reformatories to the great relief of many homes, of the order and safety of our streets, and to the advantage of public morality and decency. Many of these are mentally deficient and degenerate and are unimprovably refractory. The last Act which became law in 1903 gave inebriates a further chance of improving by three years' abstention on the "black list" at large rather than undergo detention. It also made it possible for a wife to be separated from a drunken husband and for a wife before separation to go voluntarily into a retreat with a view of reforming.

Claybury.

CONTRIBUTION TO THE SERO-THERAPEUTIC TREATMENT OF ANTHRAX: TWO CASES OF GENERAL ANTHRAX INFECTION IN MAN CURED WITH ANTI-ANTHRAX SERUM.

By Professor Dr. IVO BANDI,
LECTURER ON HYGIENE AND BACTERIOLOGY IN THE UNIVERSITY OF BOLOGNA.

In deciding how far a specific treatment is really effective in a disease which is not necessarily fatal, as, for instance, anthrax in man, I believe that it is of the utmost importance to record those cases (by no means rare in practice) in which that treatment has been used under conditions of extreme gravity when the morbid process has become generalised, and in which also clinical observations have been accompanied by the strictest laboratory experiments. I propose to give a detailed account of two cases of general anthrax infection, proved to be so bacteriologically, and successfully treated by me with anti-anthrax serum at St. Paul, Brazil. One of them will be seen to have been of exceptional severity. I shall describe briefly the mode of preparation of the serum, its specific strength, and indicate certain rules which should be observed in the special cases when it is injected into the human subject. Its preparation was commenced in February, 1902, at the Bacteriological Institute of the State of St. Paul. The method followed was the same as that which I had used in preparing the bactericidal antidiphtheritic serum—viz., inoculation in gradually increasing doses of "sensitised" anthrax bacilli alternately with injections of older anthrax cultures in broth to which had been added, in accordance with Sclavo's method, 5 per cent. gelatin, with the intention of also inoculating in all probability considerable doses of the toxic products of the anthrax bacillus. Each inoculation was followed by one of anti-anthrax serum in doses of from 10 to 15 cubic centimetres until the animal from which the serum was to be obtained had acquired a decided resistance to the anthrax bacillus and its toxic products. To "sensitise" the germs and for the protective inoculation Sclavo's serum proved of the greatest use. I chose the sheep as the animal from which to obtain the serum for the reason, that although less resistant than the mule, its smaller value allows the experimenter to render immune a great number of animals simultaneously. Sclavo has shown that this is absolutely necessary also in the case of the ass, the activity of the serum differing in one individual and another. Some animals even after quite a long period of immunising treatment furnish a serum almost destitute of specific properties. By the above method I obtained from a sheep of about 30 kilogrammes in weight after one and a half months' treatment a serum possessing considerable antibactericidal and antitoxic activity. To determine its bactericidal power in vitro, following Bordet and Gengou's method for determining the presence of immune bodies and specific agglutinins, I placed given dilutions of serum in normal physiological salt solution in contact with emulsions of scrapings from the surfaces of recent agar cultures of anthrax bacillus filtered through paper in the same way as was done by me for the bacillus of diphtheria and bubonic plague, these being, like the anthrax bacillus, germs that normally develop well in the liquids used for cultivating them. The anti-anthrax serum thus prepared attained a high proportion of immune body, as could be easily shown in vitro. Its agglutinating power on the anthrax bacillus attained a maximum of 1 in 40—a high figure when the low agglutinating power and the small agglutinogenous properties of the anthrax bacillus are borne in mind. The very active anti-anthrax serum prepared by Sclavo rarely attained a higher agglutinating value. To test the preventive and curative value of the serum I made use of Sclavo's method—viz., intravenous injections in the rabbit of from three to five cubic centimetres of serum simultaneously with subcutaneous inoculations of one-half to one cubic centimetre of a dense emulsion of anthrax bacilli made by diluting with distilled water scrapings from the surfaces of young agar cultures. This amount of virus was invariably sufficient to kill the control animals within 48 hours. In the various experiments made I was always able to save at least one-half of the inoculated rabbits. The susceptibility of the rabbit to anthrax is, as is well known, so great that this result may be considered extremely good. There is no experimental method by which to determine exactly the antitoxic power shown by the anti-anthrax serum, mainly because we have not yet succeeded in preparing a true anthrax toxin and are ignorant how far the products derived from cultures of the anthrax bacillus resemble in constitution and in effect the toxic products elaborated by the same bacillus in the living organism. Anyone, however, who has had occasion to make use of a properly prepared anti-anthrax serum in exceptionally severe cases of anthrax in man can easily assure himself of the existence in this serum of energetic antitoxins. In serious cases of this kind the toxic phenomena are evident and very distinct but after the use of the serum they diminish and disappear with [illegible] This was my experience in the two cases [illegible]

Before giving a detailed description of these two clinical cases and of the specific serum treatment adopted I shall touch upon a special detail in the injection of the serum in man. This detail concerns only such severe cases as necessitate intravenous injections of serum in large doses. Here perhaps I am not in agreement with all those who have treated the subject. Sclavo, for instance, thinks that the activity of the serum to be inoculated alone should be considered, which acts first of all as an energetic excitant of the natural powers of defence possessed by the organism. Although we may admit the fundamental truth of this principle, we must nevertheless remember that in cases of exceptional gravity, treated at an advanced stage when little reliance can be placed in the power of reaction of the organism against the disease, there is no reason why we should not attempt as complete and rapid a neutralisation as possible of the toxins circulating in the system. The two cases to be described prove incontrovertibly the correctness of this theory; and I therefore feel myself justified in recommending that in cases of anthrax in man which show a decided tendency to generalisation, and especially in such as are marked by the phenomena of poisoning (diffused œdema, disturbances in the circulation, renal lesions, &c.), abundant intravenous injections of the anti-anthrax serum should be made. Moreover, my own experience shows, what others have already observed, that these intravenous injections of serum when carefully made even in large quantities give rise to no serious disturbance in the patient, and this is a further argument in favour of resorting to them in desperate cases. The practical detail in the method of injection referred to above relates to the large doses of serum which must be inoculated in these cases, for following as I did Sclavo's method of preserving the serum by adding to it ether in the proportion of 3 per cent. there is the risk of introducing into the veins with a large dose of serum a considerable amount of ether and this might be harmful. To obviate this danger I act as follows. A common glass vessel (an ordinary table glass will suffice) is boiled together with some squares of gauze. After the ten minutes' boiling necessary for sterilisation the vessel is removed from the water with its mouth covered with the gauze. As soon as the temperature of the vessel has sunk to about 104° F. the serum to be inoculated is poured upon the gauze and filtering through into the vessel below is freed from the precipitate which, especially if not of recent preparation, is always present more or less and which might be harmful if injected into the veins. It is freed also of the greater part of the added ether which rapidly evaporates, especially if the glass is well shaken. I introduced the serum thus prepared very slowly into the veins of the patient, pressing down the piston of the syringe little by little, so that I was able in the following two cases to inject large quantities (as much as 150 cubic centimetres at [illegible] results.

[illegible] 30 years, a cattle-[illegible] h, 1903, at 11 A.M., I was called by the medical man in attendance (Dr. Sodini) to examine the patient and to treat him with serum should it appear advisable. I was informed that the man had observed on August 4th a small pimple attended with itching in the middle third of the flexor surface of the right forearm. Having no suspicion of the gravity of the case he had poulticed the affected part and had not called in a medical man. The same evening he became feverish and becoming rapidly much worse medical attendance was sought on the following morning (the 5th). Dr. Sodini found the patient with a temperature of 105° F., very much excited, and his pulse frequent and irregular. The right forearm was very œdematous, the skin was stretched and reddened, and in the middle third of the flexor aspect there was a pustule with a necrotic centre surrounded by a broad bluish band. The epitrochlear glands were very much swollen and in the right axilla a gland was seen of the size of a nut and painful to the touch. Dr. Sodini recognised that he probably had to do with an exceptionally serious case of external anthrax showing a tendency to rapid generalisation. Dr. A. Vieira de Carvalho and Dr. Pereira da Rocha were called in [illegible] external [illegible] it was d[illegible] local action of the thermo-cautery, although liberally used, on the 8th (three days after the application of the thermo-cautery) declared the case desperate and decided unanimously to call me to try, as *ultima ratio*, the use of the serum.

When I saw the patient at 11 A.M. on the 8th he was in a state of coma. His pulse was rapid and intermittent and the temperature was 104°. For the last 24 hours he had passed very small quantities of turbid urine, which was found to contain a large amount of albumin. The microscopical examination of the sediment showed in addition many granular casts and red corpuscles. The right arm was enormously swollen; the œdema had spread to the shoulder and even to the edge of the great pectoral muscle. In the right axilla was a swollen gland of the size of a hen's egg, hard and extremely painful to the touch. All round the large necrotic zone due to the very free use of the thermo-cautery were several vesicles of varying size filled with a serous, slightly turbid liquid. From the fluid in them microscopic preparations and cultures in broth and in agar were made. 20 cubic centimetres of blood were drawn from the middle vein of the left arm at the bend of the elbow. From one portion of this blood microscopical preparations and cultures in broth and agar were made and from the other cultures in gelatin. After this I injected 150 cubic centimetres of anti-anthrax serum into the middle vein of the left arm. The microscopical examination of the exudation drawn from the vesicles showed the characteristic anthrax bacillus; that of the blood gave a negative result. Anthrax bacilli developed in all the tubes of agar and broth inoculated with blood; the gelatin plate cultures gave an average of 12 typical colonies of bacillus anthracis per cubic centimetre. This bacillus was then sensitised with anti-anthrax serum, which agglutinated it in the proportion of 1 in 30 in the space of an hour. It killed guinea-pigs of a weight of from 400 to 450 grammes in 72 hours with the characteristic symptoms. On the evening of the 8th I visited the patient again. About an hour after the inoculation of the serum he had had a slight access of dyspnœa, had been delirious, and had perspired profusely. These same manifestations, and especially the profuse diaphoresis, I remember to have observed almost invariably in cases of bubonic plague at the Hospital for Infectious Diseases at St. Paul after intravenous injections of large quantities of anti-plague serum. The pulse was less frequent and irregular than it was in the morning; the swollen gland was still hard and very sensitive to the touch. A second intravenous injection of 50 cubic centimetres of anti-anthrax serum was made. About two hours after the injection there was again profuse sweating. The patient passed a somewhat disturbed night. Urine was abundant. The patient on the morning of the 9th [illegible] in the early hours of the [illegible] vas sensibly improved. The pulse was [illegible] hat frequent; the temperature was 101°. The urine, abundant during the night, was limpid and there was a very slight trace of albumin, while the microscopic examination of the sediment obtained by centrifugalising showed but few granular casts and red blood cells. The œdema in the arm was considerably diminished; the axillary gland was less swollen and had almost ceased to be painful on pressure. I thought it advisable to continue the treatment with serum and injected under the skin of the abdomen 40 cubic centimetres of anti-anthrax serum. He had a quiet day, had many hours' sleep, and the kidneys acted freely. On the 10th his general condition was good; the pulse was normal and the temperature was 98·5°. The examination of the urine for albumin and for renal elements was negative. The œdema was confined to the forearm, round the large necrotic area caused by the action of the thermo-cautery; the axillary gland had ceased to be painful and had diminished to the size of a nut. I took 15 cubic centimetres of blood from a vein of the left arm. With a portion of the blood cultures in broth and agar were made and with the other part, after defibrinating it, I inoculated three guinea-pigs, two under the skin and the third in the peritoneum. All these tests gave negative results. On the 11th the patient had passed a very quiet night; the general conditions continued good, the examination of the urine showed nothing abnormal, the œdema had almost completely disappeared, and the gland in the armpit was hardly to be felt. On the 12th the patient's condition could not be better; he was very hungry and he had slept quietly. He might now be considered fairly convalescent and bore no trace of the severe infection he had been through beyond considerable weakness and the great wound opened by the thermo-cautery, the closing of which would naturally require a long time. I saw the man again after he was completely healed of his wound. He felt no further effects of his illness.

CASE 2.—The patient was a man, aged 27 years, a butcher at St. Paul. On the evening of Oct. 2nd, 1903, I was called in haste by Dr. F. Buscaglia to treat with serum a serious case of malignant pustule which he was then attending. The patient presented in the middle third of the flexor surface of the right forearm a characteristic pustule of the size of a two-centime piece with vesicles and surrounded by a broad violet zone. The whole of the forearm was much swollen; the epitrochlear glands were swollen and painful and in the right axilla was a swollen gland of the size of a pigeon's egg and very painful to the touch. The patient's general condition was somewhat serious. The pulse was frequent and irregular and the temperature was 103°F. The patient was very restless and complained of a burning sensation where the pustule was and of a sharp stabbing pain in the right axilla. He had passed very little urine during the preceding 24 hours; the urine was slightly albuminous; it contained no casts. The pustule was cauterised with the thermo-cautery, after which I made an intravenous injection of 80 cubic centimetres of anti-anthrax serum and a subcutaneous injection of 30 cubic centimetres in the abdomen. Preparations made directly with material taken from the pustule showed the characteristic anthrax bacilli. In the gelatin plate cultures, made with blood, appeared typical colonies with an average of seven colonies per cubic centimetre. This bacillus was characteristically sensitised and agglutinated by anti-anthrax serum; it was virulent when injected into guinea-pigs. On the 3rd he was very restless during the first hours of the night and perspired profusely. Towards morning he fell asleep and slept soundly for nearly four hours. His general condition was good; his pulse was regular, his temperature was 98·5°, and his kidneys acted freely. There was no albumin in the urine. Examination of the blood revealed no bacteria. The œdema of the affected arm was considerably diminished and the glands were almost normal in size; the axillary gland had diminished in size and was painless to the touch. Having obtained so sudden and decisive an improvement I thought it unnecessary to continue treatment unless anything unforeseen should again render it necessary. On the 14th the condition was excellent; he slept well; the œdema had almost completely disappeared and the glands were almost normal. The rapid improvement continued and after four days the man went back to work.

Examination of these cases clearly proves that, although isolated, they give stronger support to treatment with anti-anthrax serum than is to be drawn from a long series of cases of simple external anthrax successfully treated with anti-anthrax serum at the outset under conditions which leave it doubtful whether the usual local treatment destructive of the original seat of infection might not have been of itself sufficient to arrest the progress of the disease. In both the cases described the clinical and bacteriological examination confirmed the diagnosis of exceptionally severe general anthrax. In both cases, but especially in the first, the serum was used when the signs of serious general poisoning were chiefly apparent in the œdema which had spread far from the primitive seat of infection, in grave disturbances of the circulation, and in the evident lesions of the kidneys. Moreover, in the first and without doubt the most serious of the two cases the action of the serum was rapidly decisive when free cauterisation of the primitive seat of infection had completely failed. The double action of the anti-anthrax serum, antibacterial and antitoxic, is plainly evident, its antibacterial power shown by the immediate arrest of the progressive invasion of the organism by the bacillus, and its antitoxic power by the sudden improvement in the general condition of the patients and by the complete *restitutio ad integrum* of the renal function immediately after the use of the serum. I would insist on the necessity of treating such severe cases energetically by injecting into the veins large doses of the specific serum. For while, on the one hand, no justifiable opposition can be made to the treatment when carried out with proper caution, in the practical result its antitoxic action as shown pre-eminently in the first of the above cases was so immediate as to suggest rather a rapid neutralisation of the toxins circulating in the system than a stimulating action of the specific principles contained in the serum on the natural defensive powers of the organism.

Bologna.

CASE OF REMOVAL OF THE APPENDIX ON A ROYAL MAIL STEAMER AT SEA; RECOVERY.

By T. H. MACFIE, M.B., C.M. EDIN.,
SURGEON, ORIENT PACIFIC LINE.

OUR chief engineer, aged 44 years, was taken ill on May 10th, 1904. We were then four days out from Suez and Colombo, our next port of call, was distant six days. He complained of pain in the bowels and felt sick and disinclined for food. He had a normal pulse and a temperature or 99° F. The bowels had moved during the day and he had not vomited. There was tenderness in the right iliac fossa but nothing could be felt. He had been liable to attacks of pain in this region for some years and when a junior engineer he used to seek relief by leaning against some hot pipes in the engine room. These attacks had become gradually more severe; the last one, nearly two years ago, necessitated his being in bed for over a week. There was a history of two attacks of typhoid fever. On the 11th he complained of more pain. The morning temperature was 99·5° and the pulse was 100 and of fair strength. There were more tenderness in the right iliac region and some resistance on pressure but no tumour could be felt. The percussion note was clear and a rectal examination disclosed nothing. During the day he was given two three-grain calomel powders and later two rectal injections of warm water, after which the bowels acted. Dr. Milne of Sydney, a passenger by the steamer, kindly saw him with me at night. The temperature then was 103°, the pulse was 108, and the local condition remained unchanged. We agreed as to diagnosis and decided that operation was not then indicated.

We saw the patient again together on the morning of the 12th. He had passed a restless night and looked worn and anxious. The temperature was 104° and the pulse was 110 and weak. During the night he had had an attack of shivering and he had vomited twice. The local tenderness had not increased; if anything there was more resistance on pressure but still no swelling could be felt. We now advised an operation as the only means of affording relief and having obtained the patient's consent we made the necessary arrangements to have it done in the ship's dispensary at 2 P.M. We were then in latitude 10.20 N., longitude 59.30 E., distant some 1222 miles from Colombo. Excepting an atmospheric temperature of 92° the weather conditions were favourable and promised to remain so. Dr. Milne gave the anæsthetic (equal parts of chloroform and ether) and the chief steward (Mr. Rigden) assisted at the operation. The abdomen was opened by an incision four inches long, having for its centre McBurney's point. The omentum was not adherent and only a few adhesions were found round the cæcum. The appendix was found behind the cæcum with its free end pointing towards the umbilicus. It was two and a half inches long, very much inflamed, and its terminal portion was distended. About its centre there was a patch of yellow necrosed tissue of the size of a pea. It was packed round with sterilised gauze, ligatured half an inch from its seeming base, and cut off. In doing so some thick offensive material escaped on to the gauze packing. On examining the stump afterwards a portion, firmly adherent to the cæcum, was discovered. This was separated, a fresh silk ligature was applied, and this portion was then removed. The stump was touched with pure carbolic acid and the peritoneum was stitched over it with a fine silk suture. The abdominal wound was closed with three layers of sutures and a cyanide gauze dressing was applied. At night the temperature was 101° and the pulse 108 and he seemed comfortable.

The patient had severe chloroform sickness for three days after the operation; ice, hydrocyanic acid, chloretone, and creasote were tried without any benefit resulting. Rectal feeding was resorted to and this, with hypodermic injections of morphine (one quarter of a grain) and atropine ($\frac{1}{150}$th of a grain) kept the sickness in check. The temperature on May 13th was 98°; it reached 100° on the 15th, after which it fell to normal. The bowels acted on the 17th after the administration of three grains of calomel by the mouth and two rectal injections of warm water and turpentine. The wound was dressed on the 19th when two stitches were removed. On the 21st some discharge was coming from the wound where a stitch had been removed. On the 23rd all the stitches were removed; the discharge was less in amount and the wound looked healthy. It was dressed daily until June 3rd when it had quite healed.

I take this opportunity of thanking Dr. Milne for his ready coöperation during the critical period of the case, for without his assistance an operation would have been impossible.

A NOTE ON HOME-MADE "HUMANISED" MILK.

By C. BEAUCHAMP HALL, F.R.C.S. ENG.,
DISTRICT SURGEON TO THE CITY OF LONDON LYING-IN HOSPITAL.

VARIOUS methods have been from time to time brought forward and advocated for the rearing of artificially fed infants with more or less success. The following method of making home-made "humanised" milk, provided the instructions are properly carried out, has proved extremely satisfactory in my hands. I think the method is worth recording not only on account of its success but because every year the number of infants who have to be reared in this way seems to be on the increase. In a very small minority of these cases the mother has no milk or a very small quantity, or else it disappears on her resuming her everyday life. In a few cases breast-feeding has to be forbidden on account of breast troubles, anæmia or debility in the mother, or an inferior quality of milk. Very frequently, however, I find that the mother will not nurse her infant for one reason or another. It is our duty to endeavour that every infant shall develop into a healthy child as the result of our advice in this direction, whatever the cause may be of its being denied its natural food. For some years I have employed one or another of the methods hereafter described with slight modifications in practice. The results have been good provided the few simple rules are carefully followed.

The following are my reasons for preferring a home-made article. 1. Dairy-made "humanised" milk may after manufacture presumably become as easily contaminated as ordinary cow's milk, whereas if we start with sterilised cow's milk and guard against contamination we are certain of a pure article at the finish. Moreover, contamination is far more probable at a dairy than at home, if for no other reason because the process mus [illegible] 2. We cannot be certain of t [illegible] "humanised" milk or of the [illegible] and in my opinion the latter has an important bearing in cases of failure. 3. On several occasions I have had cases of diarrhœa following the consumption of dairy-made "humanised" milk which have ceased on substitution of the home-made article. 4. Expense in some cases has to be taken into consideration. Dairy-made "humanised" milk costs 8*d.* a pint. The home-made variety in addition to the ordinary price of cow's milk costs about ½*d.* a pint and occupies about 20 minutes a day.

As I have said before, mother's milk is the natural food of infants and it follows that as close an imitation of this natural food as we can [illegible] stitute for it. Syntheti [illegible] caseinogen, fat, sugar, a [illegible] together with water, and [illegible]; but—and this is one of the greatest faults of patent foods—there is an indescribable element lacking which no chemist or physician can manufacture. I refer to the natural element of freshness which gives to breast milk in a healthy mother preventive power with regard to rickets and infantile scurvy. Cow's milk, along with other natural foods, contains this fresh element and therefore every food for the artificially reared infant must have cow's milk as its basis. The artificially reared infant starts at a disadvantage compared with the breast-fed infant and the substitution of any other basis and absence of this fresh element mean sooner or later the production of anæmia, rickets, or scurvy. A bad start during infancy will always leave a lasting mark in the after race *for life.*

[illegible] habit of prescribing [illegible] I have stated above [illegible] to this food occurred, and as a few of the babies were of the flabby, anæmic type, without definite rickets, I sought out some different process of manufacture. Being convinced absolutely that in theory "humanised" milk was far and away the best food, it was in the practice—i.e., the manufacture of it—that I surmised the fault lay. My first object was to obtain a pure and trustworthy preparation of rennet and having succeeded in doing so to standardise it. My object in standardisation was to save unnecessary expense, owing to the difficulty in obtaining an absolutely pure article. The rennets on the [illegible] ariable preparations and this [illegible] preparations. Of these, some- [illegible] times the amount is required [illegible] milk as is required at other [illegible] which they are made may not [illegible] therefore, a powdered form of rennet is the best. This is purified and standardised. Formerly I used a powder mixed with two grains of bicarbonate of sodium, but now I believe the method is still further improved by making the powder into a compressed tablet, thus insuring accuracy. Each tablet, besides containing sufficient rennet to curdle half a pint of milk, contains one and a half grains of bicarbonate of sodium, half a grain of calcium phosphate, and five grains of lactose. The sodium bicarbonate is added to neutralise any lactic acid formation and consequent fermentation that might result in the hot weather. The calcium phosphate is added because rennet, like other ferments, acts better in the presence of a calcium salt, also because of its remarkable action in helping tissue formation in growing children. A certain quantity is present in normal milk and this extra quantity, although small, is beneficial. The lactose is added to make up the deficiency of this substance in cow's milk as compared with human milk. Hofmann advised the addition of 110 grains of lactose to each pint. The necessity of this large quantity is not apparent. When milk is curdled by rennet 75 per cent. by volume consists of whey, the rest being curds. Now whey contains every substance in the milk except fat and caseinogen and therefore it contains lactose. Human milk contains 5 per cent. of lactose and cow's milk 3·8 per cent. (Halliburton). From half a pint of cow's milk we obtain seven and a half ounces of whey, which necessarily contains 3·8 per cent. of lactose. By adding five grains of lactose to seven and a half ounces of whey and 10 ounces of milk a mixture is obtained containing the same quantity of lactose as that quantity of human milk would contain. The deficiency of fat which this mixture would contain (0·3 per cent., Halliburton) by admixture is made up for by skimming the half pint of milk that is to be curdled. These tablets then make a mixture almost identical with human milk and the instructions for their use I have ordered to be inclosed with the tablets.

The directions are as follows:—Boil or sterilise half a pint of cow's milk. Take another half a pint and skim it and add the skim to the first half pint. Crush a tablet and when the skimmed half pint has been heated to 100° F. add the crushed tablet, stir, and keep at about the same temperature for 20 minutes, separate the curd thus produced, and then boil the whey for two minutes. Add this whey to the first half pint and to this mixture add three ounces (six tablespoonfuls) of boiled or sterilised cow's milk. Soak all vessels used in boiling water before and after use. The quantities given in these directions make one pint. Mr. Felthouse of Highbury Park has manufactured the tablets according to my directions.

Compton terrace, N.

EXTRA-UTERINE GESTATION: A FULL-TERM CHILD REMOVED BY OPERATION FOUR MONTHS AFTER FŒTAL DEATH.

BY GEORGE E. WHERRY, M.C. CANTAB., F.R.C.S. ENG.,
SURGEON TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

A HEALTHY woman, aged 38 years, came under my care in Addenbrooke's Hospital with an abdominal swelling of about the size of a pregnant uterus at nine months. The swelling felt firm in some parts and in others cystic or elastic. There was resonance in the flanks. On vaginal examination the os was soft and slightly patulous; there was no firm swelling in the pelvis. The nipples were large with a dark areola and exuded on pressure a small quantity of milk. There was a small, well-marked, supernumerary nipple, with a dark areola round it, situated about three inches in a line with, and below, the left nipple. The patient had had a child 20 years ago whom she nursed at her breast during six weeks until the infant's death. She was regular in menstruation since the loss of her child until May 21st, 1903. Since this date she had seen nothing except that about four months previously there was a discharge of dark blood during several days. In July she was examined by two medical men who told her that she was pregnant. She had abdominal pain and sickness, the breasts were swollen, and she had difficulty in passing urine. In August of the same year she noticed a tumour above the pelvis. In February, 1904, she felt movements in the swelling which had risen above the navel. There were intermittent pains in the abdomen and these symptoms lasted several days. She was visited by four medical men on Feb. 22nd as she was expecting to be delivered. She felt the movements up to March, when on the 4th of that month her mother died and she felt movements no more.

An operation under chloroform was performed on July 1st. An incision below the umbilicus encountered the placenta; beneath and below this a sac of dark fluid, not ill-smelling, was emptied. A child lying in the fluid, the left arm presenting and the head in the left iliac fossa, was delivered. The placenta was removed by blunt dissection and the cavity was cleared out with sponges. The sac was firmly adherent to the bowels and much of it was therefore left behind. The left tube and ovary were of about twice the natural size and firmly adherent to adjacent intestine. The other ovary and the uterus were normal. There was little bleeding. A gauze drain was used. The patient made a good recovery.

The child was a full-term male with perfect nails and the testes in the scrotum. It was slightly macerated in places but was not putrid and was but very little discoloured or altered in appearance from that of a stillborn child delivered from the uterus. The limbs and cervical spine were unnaturally flexed and twisted.

It may be reckoned that this infant grew to full term among the intestines and lay there dead during four months. Thus there was no hæmorrhage in "peeling" away the placenta. There was no putridity, probably from the fact that the placenta was nowhere adherent to the bowels but only to the abdominal walls. In this case if an operation had been performed by the ordinary incision during the life of the child it would have been difficult to deal with the hæmorrhage from the placenta. A lateral opening in the abdomen leaving the placenta untouched would have been the best procedure.

ST. THOMAS'S HOSPITAL.

A CASE OF FEMORAL ANEURYSM IN HUNTER'S CANAL; LIGATURE OF THE SUPERFICIAL FEMORAL AND POPLITEAL ARTERIES; CURE OF THE ANEURYSM; DEATH FROM CARDIAC DISEASE TEN WEEKS LATER.

(Under the care of Mr. H. BETHAM ROBINSON.)

THE patient, a man, aged 48 years, was admitted under the care of Mr. Betham Robinson into St. Thomas's Hospital on August 19th, 1901. His father had died from a burst blood-vessel. He himself had always been a healthy man, without any history of syphilis, but owned to indiscretions with alcohol during the last four years. 14 weeks before admission he had a bad attack of pneumonia. Four weeks before he began to have very great pain in his right thigh, lasting for hours at a time, for which various remedies had been tried without any relief. During the last ten days the leg had been very swollen, more than at the present time, and he had also noticed that the swelling in the thigh pulsated.

On admission there was a fairly large pulsating tumour occupying the middle third of the thigh (Hunter's canal) which was extremely painful and tender to the touch; the pulsation was expansile. The right dorsalis pedis artery was much weaker than the left. There was double aortic disease with cardiac hypertrophy, but no evidence of thoracic dilatation. The pulse was moderately water-hammer in character and the vessels were obviously thickened. A few days' observation showed him to have an irregular temperature, never exceeding 101° F.; as to the cause ulcerative endocarditis was questioned unless due to the local condition. Dr. H. G. Turney was certain that there was no state of lung remaining to account for it. There was no albuminuria.

As the aneurysm was of rapid onset and progressive, and so very painful, Mr. Betham Robinson decided to operate. On August 28th he ligatured the superficial artery at the apex of Scarpa's triangle; the vessel here seemed quite healthy and three floss-silk ligatures were used and tied by the Ballance and Edmunds method. Any idea of excising the aneurysmal sac, if entertained, would have been impracticable as the sac was too diffuse. The ligature temporarily stopped all pulsation in the sac but before the wound was stitched up it had returned with fair force. To combat this the upper part of the popliteal was ligatured, it being cut down upon just below the opening in the adductor magnus, which procedure was perfectly successful in stopping all pulsation. The limb was dressed and well bandaged in cotton wool. On the 30th considerable pain had still been present in the leg since the operation, but it was eased by morphine. The leg was fairly warm. The temperature remained irregular. On Sept. 4th the wounds were healed and all stitches were removed. There was no pulsation in the sac; the condition of the limb was good. There was slight pulsation in the dorsalis pedis. The patient complained greatly of pain down the leg which seemed especially referred to the area supplied by the internal saphenous nerve. On the 11th pulsation was very distinct in the dorsalis pedis. There was very great pain in the leg. The temperature was irregular, ranging from 98° to 101° F. On Oct. 11th it was stated that since the last note the pain in the leg had been just as severe; whether due to this cause or not the mental condition was very unsatisfactory. On the 14th, to try to remedy the severe pain down the leg, the internal saphenous nerve was cut down on at the upper part of Hunter's canal and one and a half inches of it were resected. On the 17th considerable relief of pain had followed the resection of the nerve, but unfortunately this proved only temporary as the patient now again complained of its severity and referred it particularly to the calf of the leg. His mental condition was most unsatisfactory, bordering on maniacal, so that it was difficult to estimate the real character of his pain. On the 19th, after being in a most excited state all the night, he said that he felt very much better. On the 21st he had been quieter during the last two nights and had been able to do without morphine. He was given paraldehyde but he slept very badly. He was getting very emaciated. There was still pain in the calf of the leg. On Nov. 2nd the patient was very restless and excitable. He still complained of great pain in the calf and feet. He lay with his legs drawn up and could not be made to straighten the right one. He died quite suddenly on the morning of the 5th from syncope.

Necropsy.—At the post-mortem examination the aneurysm was so much reduced in size as to appear as a slightly enlarged vessel with very thick walls and filled with clot. Extensive aortic disease was present. The left ventricle was dilated and hypertrophied. There were atheromatous patches on the mitral valve and atheroma of the aorta and coronary arteries. The spleen was very large and soft, with a superficial scar at one spot either of infarct or gumma. The kidneys were large and firm.

Remarks by MR. BETHAM ROBINSON.—Femoral aneurysms, or those occurring from that part of the vessel supported by muscles, are rare, and particularly so those strictly limited to Hunter's canal. They have been recorded involving both this part of the vessel with the popliteal in addition, the popliteo-femoral variety. In this case it was proved, as will be shown later, that the aneurysm was not of this type. Lisfranc, in a table comprising 179 cases, excluding the aorta, gives 18 from the femoral artery, not including those in the groin, but he does not state the exact point of origin or whether the popliteal was also involved.

In the treatment of the above case the use of compression was negatived from the associated aortic disease with its attendant mental irritability. The treatment adopted was the orthodox Hunterian operation; this was succeeded by immediate return of pulsation in the sac. To what was this rapid recurrent pulsation due? This is usually attributed to a free anastomosing circulation through a vessel communicating with the sac. Here it was very probable that the anastomotica magna did communicate with the sac, but the pulsation could not have b[illegible] why did ligature of the popli[illegible] arteries stop the pulsation? [illegible] is considered unlikely for pulsation to be transmitted to the sac through the lower end of the vessel, but yet in face of the facts it looks as if such were the case. We must suppose that there was such a free anastomosis between the descending branch of the external circumflex and the articular vessels already established that the heart's contractions were able to be transmitted to the contents of the sac.

It may be urged that the ligation of the popliteal artery was unnecessary, as the pulsation would have ceased in a short time, as is considered to be the usual sequel; it must be borne in mind that there was also a probability in the other direction and the pulsation was very free. The adoption of a novel and what seemed a more certain course of action did not appear to be fraught with any danger and was putting the patient in much the same position as in excision of the sac after ligaturing above and below.

The effect on the sac is worth noting. It will be remembered that the sac was an ovoid one of very rapid formation and the presumption is that with this dilatation there had been next to no deposition of hard clot. The soft clot shut up in the sac with the vessel's wall underwent such rapid shrinkage that at the necropsy ten weeks later the only evidence where the dilatation had been was a slightly dilated vessel with very thickened walls.

As to the cause of the aneurysm it would appear that it was embolic. There were old vegetations on the aortic valves and superimposed on this was recent endocarditis. The irregular temperature with pneumonia suggested that this was infective and the acute development of the aneurysm was in accordance with such a view.

The only other point for consideration is, What was the nature and origin of the severe pain in the leg? For a time I suspected the possibility of inclusion of the nerve in the ligature but the painful area was not defined enough; it was proved subsequently not to be the origin, because the nerve was shown not to have been included and resection of a portion of it did not remove the pain. It is possible that the attacks of pain were due to arterial spasm or arterio-sclerosis, the symptoms being allied to those met with in the condition of "intermittent claudication," first described by Charcot and more recently by Osler, Levy, and Riesman.

MANCHESTER ROYAL INFIRMARY.

A CASE OF ANEURYSM OF THE SUPERFICIAL FEMORAL ARTERY; LEAKAGE; LIGATURE OF SUPERFICIAL FEMORAL AND SUBSEQUENTLY OF PROFUNDA AND ILIAC ARTERIES WITH INCISION OF THE SAC.

(Under the care of Mr. G. A. WRIGHT.)

FOR the notes of the case we are indebted to Dr. W. F. Shaw, house surgeon.

The patient, a man, aged 53 years, a bricklayer, was admitted to the Manchester Royal Infirmary on Sept. 28th, 1903, suffering from a large [illegible] the left thigh. He had been i[illegible]s on his left thigh while he brok[illegible] first noticed a numbness in his left thigh about six weeks previously to admission and a month later had what he describes as "inflammation" in that thigh—that is, the thigh became swollen and dark coloured but settled down with rest. A short time after he had a similar attack and went to the infirmary.

On admission the patient was a healthy-looking man. There was a large even swelling on the inner and anterior aspect of the left thigh at the junction of the upper and middle thirds. Measured six inches below the anterior superior spine of the ilium the left thigh was 21½ inches in circumference and the right thigh was 18¼ inches. The swelling looked about the size of a small melon but its edges were ill defined, especially at the sides. The skin over it was smooth and not discoloured nor was it marked by any enlarged veins. The swelling was uniformly elastic and was not adherent to skin or bone; it had a slight expansile pulsation. There was no difference in the pulsation of the arteries of the legs below the level of the swelling. Aneurysm of the superficial femoral artery was diagnosed but the patient refused to be operated on, so was kept quietly in bed. On Oct. 13th, a fortnight after admission, he had severe cramp in the calves of both legs and the swelling was found to be increased greatly and very painful. He now consented to undergo an operation which was immediately undertaken.

The operation was performed under ether on Oct. 13th by Mr. Wright. A vertical incision about one and a half inches long was made, with its centre about one inch below Poupart's ligament. An artery, which was supposed to be the common femoral, was isolated and tied with double ligatures and a "stay knot." The tumour was still found to be pulsatile and on dissecting deeper another large artery was found. This was evidently the profunda, which was abnormally large and came off very high up, so that the artery first tied was the superficial femoral, not the common femoral. A ligature was passed round the profunda but not tied as pulsation had now ceased. The wound was closed and dressed and the patient was put back to bed with the leg wrapped up in cotton-wool and hot bottles were placed round it. The circulation in the toes was well maintained though pulsation in the arteries about the ankle could not be felt. On the 16th the ligature round the profunda artery was removed and on the 20th the sutures were removed, the wound being quite sound. The swelling in the thigh, however, had not gone down, though there was no pulsation to be felt in it. By Nov. 12th the swelling was softer but had not gone down in size, so an elastic bandage was applied with cotton-wool over the swelling. The patient refused to have another operation performed, so was sent to the convalescent hospital, the swelling in his thigh being then as large as on admission though not so hard and not pulsatile.

On Jan. 27th, 1904, the patient was readmitted as an urgency case, the thigh now measuring 24½ inches, as against 21½ inches when first admitted. The consistence was uniformly hard and elastic without any pulsation. There was slight œdema of the leg below the knee. No enlarged glands were present in the groin or the abdomen. There was no cough, hæmoptysis, or hæmaturia. The patient was pale and had evidently lost flesh since his discharge. The general diagnosis was sarcoma though Mr. Wright stuck to his original diagnosis of aneurysm.

Operation was performed on Jan. 29th by Mr. Wright. A vertical incision was made into the mass which proved to be a large aneurysmal sac containing old blood clot. After the clot had been cleared out some oozing took place from the walls of the sac; the profunda artery was ligatured [illegible] incision was [illegible] iliac artery [illegible]th a "stay [illegible]res and the sac was stuffed with iodoform gauze. The patient was put back to bed with the leg well wrapped up in cotton-wool and hot bottles placed round it. He did well after the operation, circulation in the foot being well maintained. A week after operation the stitches in the upper wound were removed and the packing was changed in the lower one. Unfortunately the lower wound became septic but cleared up in a few days under fomentations. The wound in the sac gradually healed and on March 4th the patient was discharged to the convalescent home with only a small sinus. He was seen in April with the wound quite sound. In July he returned; the site of the aneurysm was satisfactory, but he had apparently had an attack of cellulitis following thrombosis about the ankle. This had given rise to extensive suppuration in the leg and disorganisation of the knee-joint. Amputation was refused and he left the hospital in spite of all persuasion.

Remarks by MR. WRIGHT.—There were certain difficulties in this case which perhaps justify its record. It was difficult to persuade the man that his condition was serious and he conditions under which they live. And with regard to the disease it is pointed out that European immigrants, with a physique much reduced by tuberculosis and incapable of finding suitable work and wholesome food on arrival, are a grave source of danger to the persons with whom they associate. Such persons on whom pulmonary tuberculosis has taken firm hold should be deterred from going out to the colony or, at any rate, a sanatorium should be erected to which they might go on first landing for a short stay for the purpose chiefly of being educated as to their mode of life with reference to their disease. The birth-rate amongst Europeans was 29·31 per 1000; the death-rate was 12·90, against 14·40 for 1902, showing a reduction of 1·50 per 1000. As regards the excessive mortality in certain estates and mines which was brought to notice last year this has improved, the mortality figure having fallen well below the mean. Included in Dr. Hill's report are those from the health officers of various towns and districts of the colony. The whole volume gives us a concise account of the vast amount of good work that is being carried out by our countrymen in South Africa.

Social Diseases and Marriage: Social Prophylaxis. By PRINCE A. MORROW, M.D., Emeritus Professor of Genito-Urinary Diseases in the University and Bellevue Hospital Medical College, New York. London: Sidney Appleton. 1904. Pp. 390. Price 15*s.* net.

THE dissemination by marriage of venereal disease involves consequences which affect the health of the contracting parties, the lives of their children, and the peace, honour, and happiness of the family. The important relations of gonorrhœa with marriage have been practically ignored by the medical profession until lately; but we now know that in view of the extensive prevalence of the gonococcus, its conservation of virulence after apparent cure, and its tendency to invade the uterus and adnexial organs, with results often dangerous to life and destructive to the reproductive capacity of the woman, gonorrhœa overshadows syphilis in importance as a social peril. It is the object of the writer of this work to set forth the dangers introduced by venereal diseases into marriage and to indicate the most effective means to prevent these dangers or to limit and circumscribe their spread. This protective duty, which has for its object the preservation of the helpless and innocent from infection, devolves upon the physician in his capacity as sanitarian and guardian of the public health. In safeguarding marriage from the dangers of venereal diseases the physician becomes the protector of the wife and mother and the preserver of future citizens to the State. The situations created by the introduction of venereal diseases in marriage are many and complicated; in dealing with these situations there must be not only a thorough knowledge of these diseases in all their relations but also a knowledge of human nature.

The book is divided into three parts. The first part deals with the biological, sociological, and medical aspects of the whole question, including humanitarian considerations, and pointing out the consequences of venereal diseases when introduced by marriage upon the wife and the offspring. The social miseries thus engendered are detailed as well as the attitude of society towards these evils and the responsibility of the medical profession. The second part treats of syphilis and marriage and the third part discusses fully social prophylaxis. The author supports Neisser in his contention that gonorrhœa is a more potent factor in the depopulation of countries even than syphilis. Neisser regards gonorrhœal infection as responsible for more than 45 per cent. of sterile marriages. In the section on Social Prophylaxis the causes of prostitution are examined and certain remedies are suggested, special prominence being given to moral and educational influences, which promise to be the most efficient and are at the same time immediately available.

The most practical question discussed is when a physician may permit a man to marry who has previously contracted gonorrhœa or syphilis. In general terms it may be said that the duration of the period of prohibition is measured by the period during which the diseases are contagious and transmissible. In the case of gonorrhœa the risks of contagion may, the author holds, be determined with comparative certainty by a bacteriological examination of the urethral secretions. If gonococci are present the patient should not marry; if absent he may. While observation shows that in the large majority of cases the contagious activity of syphilis and its susceptibility to hereditary transmission cease after the third or fourth year, the arbitrary designation of a period of four years from the first appearance of the chancre, as being perfectly safe for a syphilitic man to marry, irrespectively of the type of the disease or the character of the treatment, is unwarranted by science and condemned by clinical experience. Each case must be studied on its individual merits. It is chiefly in the nervous system that search must be made for the indications which point to a grave and menacing character of the syphilitic diathesis.

Though primarily intended for the medical profession, there are several parts of the book which may be studied with the greatest benefit by the public. Most important questions are answered in it on sensible lines, questions that are constantly being asked of the family medical adviser who will find in these pages much that will strengthen his opinions and add to their value.

LIBRARY TABLE.

A Few Notes on the Bacteriology and Pathology of Mediterranean Fever. (Reprinted from the "Health of the Navy" for 1902.) By R. T. GILMOUR, Surgeon, R.N., M.R.C.S. Eng. Pp. 10.—Mr. Gilmour has been attempting to isolate the micrococcus Melitensis from the blood and urine of patients suffering from Mediterranean fever for the following reasons: (1) that in wet specimens of these fluids he had come across very small motile cocci; and (2) that he did not see how the coccus could reach the liver and spleen without passing through the blood stream. After experimenting with small quantities of blood and media he concluded that large quantities of both must be used so as to dilute down the agglutinins and alexins. At first he obtained the blood from men with bad attacks of fever; later he cultivated the coccus from the blood of patients suffering from relapses. Out of 14 cases experimented with a pure culture was obtained from seven; three, although containing small cocci, would not give any growth and five were contaminated. Mr. Gilmour gives a short clinical history of each case. He states that the earliest date at which the serum will agglutinate after inoculation is doubtful in man. With regard to what is the lowest dilution that may be accepted as a positive reaction in Mediterranean fever he thinks that if a serum gives a good reaction $\frac{1}{10}$—that is to say, well-marked clumping—it may be taken as a positive reaction, especially if the agglutination is immediate or within half an hour. The highest dilution in which he has obtained a reaction is $\frac{1}{3000}$. The paper closes with post-mortem notes on four cases of Mediterranean fever.

Ueber den Schluckmechanismus. (On the Mechanism of Swallowing.) By Professor J. SCHREIBER, Königsberg. With 22 figures and two plates. Berlin: A. Hirschwald. 1904. Pp. 92. Price 3*s.*—This dissertation on the mechanism of swallowing is an amplification of some papers on the same subject that appeared in vol. xlvi. of the *Archiv für Experimentelle Pathologie.* The experiments of

Kronecker and Meltzer in 1883 on the swallowing of fluid and semi-fluid masses had apparently at last brought something like a settled statement regarding this act, which since the time of Haller has been considered as one difficult of explanation. Finality is not yet reached, for Professor Schreiber does not agree with Kronecker's view that the mylohyoid by its contraction is the chief agent by means of *which fluid and semi-fluid matter is "shot down," almost* squirted, from the mouth into the stomach. By means of careful experiments on man and by recording the movements of an object while it is being swallowed and by taking at the same time a record of the changes visible in the neck —the latter the author calls a "deirogram"—it is concluded that many muscles are concerned and coördinated for the bucco-pharyngeal act. While the mylohyoid facilitates the swallowing movement it does not begin the reflex act. The whole act of swallowing is compared to the *phases of a cardiac beat and a diagram is given to show the* stages and their duration. The actions of the constrictors of the pharynx and œsophagus are fully given and it is shown that the term "cardia" in the physiological sense should be applied to the lowest part of the œsophagus; it is rather an epicardia which closes the œsophagus towards the stomach. The author concludes that the force expended in the act of deglutition in man is very slight. This suggestive work will beget reinvestigation of the subject.

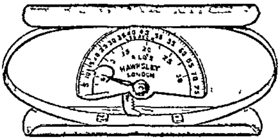
Easily Grown Hardy Perennials. By GEORGE H. VOS, M.B. Cantab. London: W. H. and L. Collingridge. Pp. 476, illustrated by 255 reproductions of photographs. Price 5s.—To those who have gardens and love flowers and have but little time to devote to gardening, the cultivation of hardy perennials affords pleasurable and delightful results with a minimum of trouble. Moreover, hardy perennials can mostly be propagated with ease by simple division and many require but little care, it suffices to leave them in the ground year after year. Indeed, we learn that Dr. Vos has in his garden quite 200 different species of hardy perennials, which reward him with fresh flowers all the spring, summer, and autumn, and this practically without any digging or planting. Dr. Vos has been very successful with the photographs illustrating his work, as the result of special treatment the flowers stand out in bold relief. And he has been no less *successful in making quite clear to the amateur what he is* to do, and how and when he is to do it, if he would provide outdoor flowers during almost the whole of the year.

New Inventions.

A STANDARD DYNAMOMETER.

THE old dynamometer of Duchenne has given place entirely to the oval form of Charrière. It is now supplied by many instrument makers and it is rare to find that any two dynamometers of similar aspect correspond in their results. They are still made with two scales, each in kilogrammes, but I think that not more than one person in a hundred of those who use such an instrument know that the outer scale is alone intended to represent the effect of pressure in the hand. The inner scale is designed to indicate the effect of traction from the two ends of the oval spring; it is practically never used for this purpose, for which it is indeed useless, because no effort thus applied can move the index through a fifth of the scale. The divisions on the inner scale really represent the effect of pressure. But the result is that some observers record from the outer and some from the inner scale without concerning themselves with the fact that 40 kilogrammes of the inner scale correspond to 105 of the outer. This, with the variations between different instruments, destroys all possibility of comparison between records. The ordinary form of this dynamometer is also most uncomfortable in use; a strong grasp is often painful.

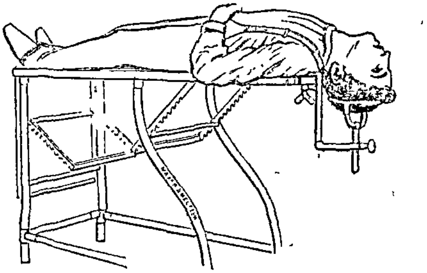
In the new instrument discomfort is prevented by a straight hollow piece of metal, semicircular in section, on each side of the oval spring, so that any force can be applied to it without discomfort. It has a further advantage in preserving the index from interference by the fingers. A *still more important feature which justifies the term* "standard" is that every instrument *is separately graduated and the scale specially engraved on each. It is clear* that only thus can trustworthy and comparable observations be secured. No attempt to produce a number of similar oval springs can result in instruments closely or even approximately the same. Every instrument for clinical observation should possess as much exactness as can reasonably be obtained and I think that this will be found true of the "Standard Dynamometer," which is made by Mr. T. Hawksley of Oxford-street.



Queen Anne-street, W. W. R. GOWERS.

A HEAD-REST FOR POST-NASAL OPERATIONS.

I HAVE found the head-rest here figured most convenient in the removal of post-nasal growths and for operations within the nostrils. The "hanging head" position over the end of the table, as ordinarily maintained, in my opinion seriously impedes respiration owing to the extremely *strained condition of the anterior neck muscles. My head-rest* overcomes this difficulty and dispenses with the need of an assistant to steady and to support the patient's head. The operator sits at the end of the table, beyond the patient, and does his work in a more deliberate, satisfactory, and safe manner than is possible by other methods, while at the same time the risk from any anæsthetic is considerably diminished. (Personally, I prefer chloroform.) The head-rest is easily clamped on to the end of an ordinary kitchen table, while the "rest" itself may be quickly raised and lowered. It should be kept low to allow of full extension of the neck. A towel thrown over it after it is fixed in position will prevent soiling by blood. The whole apparatus is in parts for convenient portability in one's bag. It will also be found useful in operations on the roof of the mouth and upper jaw, in excision of the larynx, and in endoscopic examination of the œsophagus. I have designed for ready use with the head-rest a simple folding chloroform mask on which a fresh piece of lint or domette may be clamped at each operation. The head-rest has been made for me by Messrs. Mayer and Meltzer of London and Melbourne.



Melbourne. FRANK A. NYULASY.

THE LANCET.

LONDON: SATURDAY, AUGUST 6, 1904.

The British Medical Association: The Address in Surgery.

In the Address in Surgery Sir William Macewen discussed two separate subjects upon which he was well qualified to speak. In the first place he discoursed on the localisation of abscess of the brain, pointing out that the view formerly held that cerebral abscess was generally pyæmic in origin implied that it was produced by embolism of infected portions of clot. It is true that an abscess of the brain can result in this manner but it is very exceptional, for in the great majority of instances the septic cerebral processes arise by direct extension from primary pyogenic lesions of the skull bones. The recognition of this fact gives the surgeon great assistance in diagnosing the position of an intracranial abscess, for if the position of the primary septic focus is known the situation of its dependent abscess must be limited to a comparatively small portion of the brain. Thus, if, as is very commonly the case, the primary focus is disease of the middle ear the surgeon can be certain that the resultant abscess, if symptoms point to an abscess, will be found in the corresponding temporal lobe or in the cerebrum in touch with the infected path. We now know that if the septic organisms enter the cranial cavity by way of the internal auditory meatus they will give rise to a basal meningitis and not to an abscess; at least it may be said that it is extremely rare for a cerebral abscess to follow septic invasion of the cranial cavity by this path. The explanation of the fact that meningitis follows sepsis of the internal auditory meatus is that the expansion of the membranes of the brain, which ensheaths the nerves in this canal, dips into it, and thus the meningitis first appears in the meatus and thence spreads to the base of the brain. In this connexion it is of great interest to note that basal tuberculous meningitis may be the result of extension of disease from the middle ear along the same tract, the tubercle bacilli spreading from the middle ear along the internal auditory meatus to the membranes of the brain. There is yet another way in which tuberculosis of the middle ear may threaten life. The tubercle bacilli may surround and invade the neighbouring sigmoid sinus and thus may be carried all over the body, setting up a miliary tuberculosis.

A second subject dealt with by the lecturer is of no small practical importance. It is the question of the most suitable materials for ligatures and sutures. The diversity of practice in this respect is exceedingly great and the surgeon has a very wide choice. Silk and catgut have been before the profession for many years and both still are widely used. Metallic sutures were much in vogue 20 years ago but they are very little used at present for anything but suturing bones, and it is rarely indeed that silver stitches are used for the skin. Kangaroo tendon was introduced and it is even employed now by many for special purposes, as in the radical cure of hernia, though it is rumoured that much of the material sold under that name is derived from the more obvious ox. More recently silkworm gut has been brought forward and is now very largely used, especially for skin sutures. Threads composed of linen and cotton have also been praised but they are very little employed in this country. There are many considerations which should weigh with surgeons in the choice of ligatures and sutures. The first is undoubtedly that the material of which they are composed should be capable of being rendered absolutely sterile, for if this cannot be done any other virtues which they may possess are of no effect. As Sir William Macewen points out, there are two other requirements which ligatures and sutures should fulfil. They should be capable of resisting absorption as long as is needed for the complete union of the surfaces which they hold in contact, whether these be the edges of a skin wound or the walls of an artery which has been tied, and they should then be capable of speedy and complete absorption when their work is done. For if, as in the case of a silver suture, the stitch resists absorption indefinitely, or even for a long time, it can only act as a foreign body, harmless perhaps as it is aseptic, but also useless and always liable to set up irritation. The mere presence of an aseptic body in the midst of living tissues tends to cause absorption of the surrounding structures and in this way also harm may be done by persistent ligatures and sutures. The edges of wounds in the skin in healthy subjects usually require to be maintained in contact from seven to 14 days, but this is only if there is no tension, for if there be any force tending to separate the edges of the wound a longer time will be required. Where the suture has to overcome the force of muscles or tendons at least three weeks should be allowed. In the case of bones still longer is required to insure complete consolidation, for the forces which have to be overcome are much greater, especially when leverage is brought to bear on the suture, as in long bones; therefore, about four weeks are needed in the case of most sutures of bones. Even in bone, however, after a certain time the constricting band ceases to maintain contact between the fragments, and unless bony or fibrous union has occurred the suture will not prevent the separation of the fragments. Applying these desiderata to the materials in common use we find that silk is for all practical purposes non-absorbable. Silkworm gut and hair are not absorbed at all, and have been removed even seven years after having been introduced and when examined microscopically they have shown no sign of even commencing absorption. The lecturer, after discussing other materials which have been employed, came to the conclusion that only catgut answers the needs of the surgeon. It must be selected with care, as possessing the needed strength and smoothness. Further, the process of hardening must not prevent that invasion of leucocytes which is necessary for its absorption. A mixture of glycerine and a watery solution of chromic acid seems to answer best as a hardening agent; the gut produced is soft and pliable and the resistance to absorption can be increased or diminished, so that the time it shall persist in the tissues can be regulated with a great degree of accuracy. It may be stored in a carbolised glycerine solution and in the course of months or years its resisting power tends to increase.

The rate of absorption of catgut sutures varies somewhat, according to the nature of the tissues with which they are in contact. Should the part be very vascular the piece of catgut will undergo absorption rapidly, but if the tissues possess only a few vessels the rate of absorption will be markedly less. Age, also, as might be expected, has an influence, and in the young the rate at which the catgut is absorbed is appreciably greater than in the old. When a suture is tied too tightly the rate of absorption is much diminished, but the suture by its pressure leads to absorption of the compressed tissues. Should a stitch become septic it will be absorbed with extreme slowness. By the use of absorbable sutures it becomes unnecessary to disturb a dressing for the removal of sutures after they have served their function, for the part of the suture within the tissues will be absorbed and the part outside will fall off when the dressing is finally removed. It will be seen upon reference to Sir WILLIAM MACEWEN'S address, which we publish in another part of this issue, and from the remarks that we have made upon it, that the lecturer did not so much attempt to tell the audience new things as to impress upon them broad lessons in diagnosis and minor details in treatment that will be of practical service to them.

Infantile Mortality.

MR. J. THEODORE DODD, in a recent issue of the *Municipal Journal*, has approached a very interesting problem in sanitation and vital statistics by the suggestion that high rates of infantile mortality are intimately connected with the policy of certain boards of guardians in confining outdoor relief, even medical relief, within the narrowest possible limits; and he puts forward some figures which, at the very least, appear to render his contention a probable one. He quotes Sir WILLIAM CHANCE as his authority for the statement that in St. Pancras, by merely insisting upon applicants for medical orders attending before the relief committee of the South District, their numbers went down from 4246 on Dec. 31st, 1899, to 2280 on the same day in 1901, a reduction of 46 per cent. in two years only. If Mr. DODD'S views are correct, and if any reliance can be placed upon a single example, we ought to have here a case precisely in point. According to the returns furnished to the London County Council by its medical officer of health, Mr. SHIRLEY F. MURPHY, the infantile mortality of St. Pancras—that is to say, the deaths of infants under one year of age—averaged 157 per 1000 births for the ten years 1885 to 1894. For the six years from 1893 to 1898 inclusive the numbers per 1000 births were respectively 172, 145, 174, 168, 168, and 170, or an average of 166. We do not learn when the curtailment of medical orders was commenced but it was operative during 1901, in which year the infantile deaths per 1000 were only 154, and we may presume that it was also operative during 1902, when the number fell to 147, the lowest so far recorded. We cite these figures, not as justifying a conclusion either way, but as showing that other factors must not be omitted from consideration. Mr. DODD gives a list of metropolitan unions, with a word descriptive of the policy in respect of outdoor relief adopted by each in 1902, but he does not tell us how long that policy has in each case been pursued. He gives also the infantile mortality in the same unions for the ten years 1881–90 from the Registrar-General's returns and the table, as a whole, certainly displays the connexion which he thinks may be established. For its completion it obviously requires a statement in each case as to how long the "outdoor" or "indoor" policy has been predominant, to what extent it has extended to orders for medical relief as well as to relief of other kinds, and what was its immediate as well as its ultimate effect, if any, upon the infantile mortality within the union. Tables containing these facts would also require correction by reference to infantile mortality in hospitals or institutions and to the localities in which the fatal illness commenced or was contracted, as well as by an examination of the current rates in these localities and of the probable explanation of them. The tables furnished by Mr. SHIRLEY MURPHY present not only a curious sameness of infantile mortality in many districts but also fluctuations which break this sameness and for which it is by no means easy to account. Thus, for example, the infantile mortality of London as a whole stood for many years at about 160, but in 1893 it fell to 143 and immediately thereafter rose to the customary point. With the beginning of the present century it again fell and in 1902 was only 139. The question is complicated by the adoption of new district boundaries which render the tables of former years difficult of comparison with more recent ones; but, with all due allowance for this source of confusion, there seem to be many anomalies difficult of explanation. The Strand union is described by Mr. DODD as having a decidedly "indoor," and the Holborn union as having a "slightly indoor" policy and a comparison between the two does not support his suggestion. From 1885 to 1894 the average infantile mortality of the Strand was 200, and that of Holborn was 204 per 1000. The former had fallen to 171 in 1898, the latter rose in the same year to 221 and has since fallen to 129. Verily, Sir ROBERT PEEL'S famous dictum should be remembered and we must admit with him there is nothing so misleading as facts, except figures.

Our chief difficulty in accepting Mr. DODD'S opinion that a scanty issue of orders for outdoor medical relief may be productive of infantile mortality depends upon a doubt how far such relief is likely to be efficacious in the treatment of infantile disease. If the same proposition were advanced with regard to adults we should think it a probable and reasonable one. But the diseases of infants are largely due to want of breast-milk, to scanty and improper feeding of other kinds, to exposure to cold, to life in a vitiated atmosphere, and, generally speaking, to conditions against which their tender frames are unable to strive. Such conditions would seldom be relieved by a visit from the medical man, and the advice which it would be his duty to give with reference to them would only in a very few instances be effective. For the action of medicine in such cases there is but little scope and removal to a hospital would seldom be practicable. The function of the medical man would almost be limited, we greatly fear, to certification that the death was so far due to natural causes as not to reach the current standard of criminality. We should be inclined to regard at least as an enthusiast any person who really expected the visits of the parish medical officer, even if he were obtainable without the formality of an order at all, to exert any powerful influence over the rate of infantile mortality in his district. The late Sir RICHARD QUAIN was once giving evidence as to the testamentary incapacity of the maker of a disputed will. In reply to the question what was the principal indication of insanity displayed by the deceased, he replied that it was "his unwavering faith in the efficacy of the medicines which I prescribed for him." This is occasionally quoted as a proof that the great therapeutist had no belief in the healing power of drugs. But the real significance of Sir RICHARD QUAIN'S remark was that it was unreasonable to expect drugs to do their full work when all the circumstances of the patient's environment were ranged against them. And thus it is in the matter of infantile mortality. It is not belittling the efforts of the parish medical officer to point out that neither his medicine nor his advice can operate effectively in many instances against the general causes of infantile mortality.

On the merits or advantages of the "indoor" policy as a whole we are not prepared to express an opinion; but in relation to the issue of orders for medical relief it might easily become exceedingly injurious to the poor and very costly to the ratepayers. It is true, of course, that there are among the poor, as among the rich, a large number of persons who suffer from some kind of gastric or abdominal discomfort which a little alkali and a dose of some cordial tincture will for a time relieve. Such persons are the chronic patients of every good-natured medical man, and the perpetual worries of every relieving officer. They probably receive no permanent benefit but their miserable lives may be made less miserable and they are proper objects of compassion. Very likely they are of indifferent character. They take a little gin if they can get it, and then, as Bishop EARLE says, to drink and to be drunk is all one. A measure of restriction directed against such people is hardly compatible with the exerciseof Christian charity. There is, however, far worse behind. The fact that a given board of guardians discourages the issue of medical orders and places difficulties in the way of applicants for them has a distinctly deterrent effect. Those who need them do not apply. The application is put off until to-morrow in the hope that the sufferer may be better. The morrow comes and he is worse. The natural result may be that a widow and orphans become chargeable upon the parish and for this the so-called "policy" is to blame. The claim of persons falling within any proper definition of poverty to a medical order should, we think, be absolute and indefeasible; and the duty of rejecting the applicants whose illnesses were trivial or unreal should be a distinctly medical one, to be discharged as a matter of professional responsibility. It cannot be safely committed to boards of guardians.

The Surgery of the Pancreas.

THE progress of surgery is regularly continuous. It is only now and then that we can note an advance that is really epoch-making, to use a much abused expression, yet steadily year after year the progress continues. There is a very natural tendency with most of us to imagine that we have at last reached finality or at least that we have come within sight of it. In many works of surgery the author expresses the feeling that much more cannot be done, inasmuch as we have reached the Ultima Thule of surgery. The late Sir JOHN ERICHSEN, a most able surgeon and philosophical thinker, has well expressed this feeling. He says in his "Science and Art of Surgery": "I cannot leave this subject without an expression of admiration at the great advance that has of late years been made in the treatment of diseases of the abdominal viscera by surgical operation and a recognition of the merits of those surgeons who have led the advance in this department of our art and of the vast importance of the results achieved by them. But whilst thus freely recording my admiration for the successes that have been obtained, I must add a few words of caution to aspirants for distinction in this great field of practice. I would venture to remind them that an operation is not necessarily justifiable because it is practicable; that every act of operative audacity is not a triumph of sound and legitimate surgery, and that a patient's life may possibly be prolonged on conditions less tolerable than death." And again: "Operative surgery, like every other art, can be carried only to a certain definite point of excellence. An art may be modified, it may be improved, but it cannot be perfected beyond certain attainable limits. And so it is, and, indeed, must be, with surgery. There cannot always be fresh fields for conquest by the knife. There must be portions of the human frame that will ever remain sacred from its intrusion—at least in the surgeon's hands." There is doubtless a strong element of truth in these sentences. Every modification is not necessarily an improvement; every new operation is not necessarily an advance; and in so far as Sir JOHN ERICHSEN'S words imply absolute disapproval of reckless surgery we can all endorse them as readily now as we did when they were written. But we must recognise that there are possibilities of progress invisible to us and that methods almost incredible now may become mere commonplaces to succeeding generations. In short, as no one can say what the "attainable limits" of surgery may be, the possibilities of surgery must remain unlimited.

In THE LANCET of July 9th, p. 106, we quoted a paragraph from THE LANCET of July 8th, 1826, in which Dr. CLUTTERBUCK in a lecture dealing with the diseases of the pancreas, delivered nearly 80 years ago, said: "Little need be said upon this subject because it is hardly possible to discover the existence of disease in this organ during life so as to distinguish it from that of the neighbouring parts." We have advanced very far from the state of knowledge exhibited in this excerpt both in the medicine and surgery of the pancreas, yet the greater part of this advance has occurred within the last ten or 15 years. For instance, in a valuable Dictionary of Surgery published in 1886 the word "pancreas" does not occur as a heading. From the medical aspect various morbid conditions of this organ are now known, but most of the work on the subject is recent. Dr. W. HALE WHITE collected all the cases of disease of the pancreas found in the post-mortem examinations at Guy's Hospital during the years from 1884 to 1897. During this period there were 6708 necropsies and in 142 of these the pancreas was found to be injured or diseased—that is, in over 2 per cent. of all cases. We now know, from these observations and those made by many other physicians and surgeons, that the pancreas is liable to acute and chronic inflammation. Of these the more important seems to be the acute form, for with its violent onset, the severe abdominal pain, the marked constipation, and the vomiting it is very liable to be mistaken for acute intestinal obstruction, and in several cases the abdomen has been opened under the influence of this erroneous diagnosis. The pancreas is also liable to a peculiar condition of "fat necrosis" and this morbid state may appear even in tissues at a distance from the pancreas itself. Hæmorrhage in disease of this organ is also not rarely met with, especially in connexion with acute pancreatitis. Primary malignant disease of the pancreas may occur and is generally first manifested by the occlusion of the common bile-duct and the gland is also not rarely involved by the extension of malignant growths from other organs. Syphilis and tubercle may also involve the pancreas and calculi are occasionally found in the duct of Wirsung. Cysts of the pancreas are also not uncommon, though the name has been somewhat loosely applied so as to include a localised ascites of the lesser peritoneal sac and cysts of the transverse mesocolon and omentum. The columns of THE LANCET for the last ten years have borne witness to an increasing knowledge of the pathological conditions to which the pancreas is liable.

Although we are now acquainted with many varieties of pancreatic disease, it is an unfortunate fact that many of the conditions are but little amenable to treatment. Medicinal therapeutic measures are of almost no value, but surgery is capable of affording relief in some at least of these morbid states. The rise of the modern surgery of the pancreas may certainly be traced to the publication in 1885 of a paper on the Surgical Treatment of Pancreatic Cysts by Dr. N. SENN of the United States. This was the first systematic account of the pathology of the organ, and Dr. SENN showed that it was possible not merely to diagnose with a fair amount of certainty the existence of a cyst of the pancreas but also that it was possible to treat it by draining without any very great risk to life. This is the chief operation performed on the pancreas, and it has been now performed sufficiently frequently for us to look upon it as firmly established. For malignant disease of the pancreas surgery can do but little. It is true that portions of the viscus have been removed when affected by extension of disease in the operation of excision of neighbouring malignant growths; and, indeed, in 1884 BILLROTH removed a cancer of the pancreas and the operation was followed by recovery. RUGGE also has been equally successful, but diagnosis of the condition sufficiently early to justify the operation is so very unlikely that it can hardly be considered feasible, though there is nothing in the operation itself to prevent it being attempted. To relieve a few of the symptoms of malignant disease of the head of the pancreas, such as the biliary obstruction which is almost always present, something can be done. Cholecystotomy or cholecystenterostomy may be performed, and though the statistical results cannot be said to be favourable yet in a few cases relief has been afforded; and should a chronic pancreatitis have been mistaken for malignant disease of the pancreas it is not impossible that one or other of these operations may prove to be productive of permanent benefit, for gradually the occlusion of the ducts may cease and the normal channel being established the abnormal opening may close. Calculi, as we have mentioned, are sometimes found in the pancreatic duct and in structure these resemble the calculi of the submaxillary gland. They may be single or numerous—in one case 300 were discovered—and successful removals have been several times effected. Chronic pancreatitis has been recognised by Mr. MAYO ROBSON as a fit condition for surgical interference and success has attended the draining of the pancreatic duct in such cases. From all this it is clear that our knowledge of the pathology, diagnosis, and treatment of lesions of the pancreas vastly surpasses the knowledge of a few years ago. How much further medical science may proceed in this direction no one can say; but there are limitless possibilities in the future of surgery, and the gap between Dr. CLUTTERBUCK'S knowledge and the knowledge of to-day may be smaller than the gap that will be found between our present teaching and the teaching of 80 years hence.

Annotations.

"Ne quid nimis."

NEWSPAPERS AND INCITEMENT TO CRIME.

IN the House of Commons on August 1st the Home Secretary was asked whether his attention had been called to a recent Old Bailey case of counterfeit coining in which the prisoner admitted that he had learnt how to make counterfeit coin from a full description of it in a daily newspaper by a criminal. Further inquiry was made whether, in view of the opinion expressed by the jury and by the Common Serjeant condemning the action of such newspaper, the Home Secretary could take any steps to prevent these facilitations of crime in future. The Home Secretary in his reply said that he had consulted the Common Serjeant, with whom he fully agreed as to the mischievous tendency of the article. He added that he considered the newspaper in question deserving of the gravest censure and that the whole question of incitement to crime by means of such articles is receiving the attention of the Home Office and of the Director of Public Prosecutions. This is good hearing and we earnestly hope that the phrase "receiving attention" is not a euphemism for shelving the question. We hope also that when the Home Office and the Public Prosecutor act they will act swiftly in one obvious direction. It is to the credit of the British press that incitements to crime seldom appear in the body of a journal, but the case is very different with the advertisement columns. All our readers will remember the numberless advertisements of pills or potions which, although they simply professed to cure "irregularities" in females, were really intended to be used as abortifacients. The insertion of such advertisements is a direct incitement to crime. And although, since our revelations and certain criminal proceedings for blackmail, they have become much less frequent, offenders do still exist and are still able to find newspapers willing to abet them in their disgusting courses. It makes no difference that in the majority of cases the "female remedies" would have no effect either in restoring the menstrual flow or in procuring abortion. The harmlessness of the potions places the advertisers and the newspapers which insert the advertisements in this dilemma. Either there is an incitement to crime or money is being obtained under false pretences. Quite enough specimens of these advertisements have come before us recently to make it clear that interference by the Home Office is urgently needed, while there are other classes of advertisements to which the official attention might be turned. The various drink "cures" and recipes for the restoration of "vitality" are in some cases dangerous swindles, and light turned upon the methods of some of the advertisers would considerably surprise the public. Revelations made in a medical journal do not come within the purview of the victims.

"FOURTH OF JULY" TETANUS.

IN the *Journal of the American Medical Association* of June 18th of this year is a special article entitled "The Prophylaxis and Treatment of Fourth of July Tetanus." After the annual celebration of that anniversary a large number of cases of tetanus occur as a consequence of the premature explosion of blank cartridges and fireworks. Last year no less than 406 deaths from this disease took place as the result of accidents sustained on the "Fourth." A mortality of over 95 per cent. in these cases indicates the futility of the treatment employed. The fatality of traumatic tetanus quoted in text-books gives 70 to 80 per cent. of deaths, therefore there is reason to believe that in the tetanus following wounds produced by blank cartridges there are fewer cases that recover. The reasons suggested for this high mortality are the youth of the patients and the unusually favourable conditions offered the bacilli by the blank cartridge wounds, so that the organisms multiply rapidly. Antitoxin was used in a considerable proportion of the fatal wounds, so that it would appear that this remedy is very limited in use in spite of its great experimental efficiency in animals and its considerable prophylactic value. Undoubtedly the earlier in the case that the antitoxin is used the better, but as a rule it is not given until the convulsions are well developed, at which time the disease has been in progress from five to 12 days. The following method of treatment, however, in the hands of those who have tried it has yielded more promising results. As soon as possible after the patient is seen general anæsthesia should be produced and the wound cleaned most carefully in order to prevent further formation and absorption of the toxin. Free drainage and access of air should be secured by loose but complete gauze packing. Before consciousness returns, or even before the operation is commenced, antitoxin should be administered. By far the best results which have been reported were obtained by those who have injected the remedy into the spinal canal. The plan adopted is to introduce the needle of the syringe into the subarachnoid space by passing it between the third and fourth lumbar vertebræ. The syringe should not be attached to the needle at this time, and between two and three drachms of the cerebro-spinal fluid should be allowed to escape. This fluid is known to be highly toxic in tetanus, much more so than is the blood serum. Then the syringe containing from 10 to 15 cubic centimetres of antitoxin should be attached to the needle and its contents slowly injected, allowing at least five minutes for the process. This should be followed by the injection with a fine needle of as much as possible of the antitoxin into the substance of, and along the course of, a large nerve trunk, preferably the one supplying the injured part. This method is based on observations concerning the paths by which the antitoxin reaches the spinal cord. After the operation and injections a subcutaneous saline infusion is desirable. The patient should then be placed in a quiet, darkened room and every possible means taken to avoid any disturbance which may excite the paroxysms. The administration of morphine, chloral, or bromides will be found advantageous. From the results already reported this mode of treating tetanus by antitoxin deserves a further trial, and doubtless the experience so obtained will be duly recorded.

THE DANGERS OF THE INDIAN RELIGIOUS FESTIVALS.

THE annual subsidence in the epidemic of plague has now begun to take place, the returns of plague mortality throughout India, though very serious, being for the time comparatively insignificant. But the yearly religious festivals, which cause an anxious time for the officials intrusted with the sanitary arrangements for these large concourses of people, have now commenced. Our Special Correspondent writes from Calcutta under the date July 16th as follows: "The extension of the railways in India has added to the difficulties. At Puri, for example, the numbers of the people attending the great car festival are increasing every year. In former times the pilgrims tramped by road but now they are conveyed by train in thousands packed like sheep in trucks. The water-supply is often deficient and polluted. Last year over 6000 deaths occurred from cholera and the outbreak in the town spread to the whole district around. The people are so ignorant and so fanatical that they prefer dying during the pilgrimage to availing themselves of medical assistance. Perhaps in the old days as many died on the road to or from Puri as now die in the city itself, but the danger which presents itself to-day consists in the widespread dissemination of the disease. The religious parties themselves have no concern for the health of the pilgrims and all the sanitary arrangements have to be made by the Government."

FRAUDULENT CLAIMS AGAINST THE EXECUTORS OF MEDICAL MEN.

A MAN named William Herbert Hilton was sentenced to nine months' hard labour at the recent quarter sessions held at Dorchester for an ingenious attempt to obtain money by false pretences from the executors of the late Dr. Sidney J. Allden of Bridport. Dr. Allden practised at Bridport in partnership with Mr. W. A. E. Hay until Dec. 31st, 1903, when the partnership was dissolved, and then alone until Feb. 28th, 1904, when he died. The usual notices of his death appeared in the medical papers, after which an account for goods to the value of £5 9s. was received addressed to him, which purported to be overdue. This would mean that the debt had been contracted by him privately during the existence of his partnership, and the fact that Dr. Allden had always been scrupulously careful in paying accounts as they fell due caused his executor, who happened to be a solicitor, to make careful examination of all his papers and receipts. A letter to Mr. Hilton, the pretended instrument-maker, who had as a telegraphic address upon his paper the suggestive, if curiously spelt, word "Chururgecos," produced an answer expressing regret at the news of Dr. Allden's death and referring to him as a fellow-student of the writer at St. Thomas's Hospital. This, no doubt, was due to the mention of St. Thomas's Hospital in the Medical Directory as a place where the deceased had received part of his medical education. As a matter of fact, however, he had only been there for six months when he was already fully qualified and therefore not a student. Inquiry showed that the prisoner had never been at St. Thomas's Hospital at all, that he had no place of business, that the addresses which he used were merely places where letters were addressed to him, and that he had not registered any telegraphic address. Upon these false pretences he was arrested and convicted, the matter being clinched by the fact that, although he defended himself with considerable pertinacity up to the last moment, he declined to enter the witness-box and give an account of himself. He would probably have cut a poor figure under the cross-examination which counsel for the prosecution was no doubt ready to administer to him. Juries are now fully aware of the right of prisoners to tell their stories under oath, and ingenious rascals who decline to face the ordeal are not likely to be believed. The story shows that the executors of professional men should be careful not to pay apparently genuine accounts without careful examination and also exemplifies the importance of keeping receipts for moneys paid, and also accounts of sums due. A noticeable feature in the trial of Hilton was the evidence of Mr. R. S. Hopkins, medical school attendant at St. Thomas's Hospital, who was able to swear positively not only that he had been unable to find the prisoner's name in the registers but that from his personal knowledge the prisoner had not been a student at the hospital within the period of Dr. Allden's attendance there or at all. No effort of the prisoner could shake him in this, and no doubt his claim to recognise the faces of all students who had attended during his service at the medical school was fully justified. The faculty of accurately remembering faces is natural to some persons and is one which can be strengthened by habitual effort. It is an extremely useful, if not essential, qualification of porters in hospitals, clubs, and other places to which admission is permitted only to members of the institution. Persons endowed with it can usually be depended upon not to make mistakes and their evidence is of an entirely different nature from that of those who readily, and often inaccurately, profess to know persons who, they allege, have upon some one occasion robbed or injured them. The case of the unfortunate man Beck, recently "pardoned" after having endured a term of penal servitude and a further arrest since for robbing women of their jewellery, will long be remembered as an instance of the ease with which mistakes may be made by casual and unpractised observers.

METRORRHAGIA IN TYPHOID FEVER.

THOUGH various hæmorrhages are common in typhoid fever uterine hæmorrhage has received little attention. Menorrhagia at the onset of the attack has been observed. In the *Journal of the American Medical Association* of July 2nd Dr. W. E. Darnall has recorded the following case, which is remarkable in that the hæmorrhage took place during the third week of the attack and did not occur at the time of a menstrual period. A woman, aged 30 years, became ill on May 21st with headache and muscular pains but she did not take to bed until June 9th. On the 12th the temperature was 103° F. and severe diarrhœa began. About 8 P.M. the temperature was 105° and metrorrhagia began. (Menstruation had occurred two weeks previously and had always been regular.) There were constant nausea and abdominal pain and the stools were of a "pea-soup" character. On the 13th there was no action of the bowels but the flow was more free and micturition was difficult. The Widal reaction was obtained. An examination did not reveal any disease of the pelvic organs. Ergot was given. The vagina was packed with gauze for 24 hours, which checked the hæmorrhage. On the 14th the temperature ranged between 101° and 103° and the pulse between 80 and 130. A few typical rose spots were seen. On the 15th the temperature ranged between 101° and 103° and the pulse between 114 and 143. The patient's condition was critical and the dejections took place involuntarily. The pulse was very weak and at times imperceptible. The stomach rejected everything. On the 16th death occurred. At the necropsy some Peyer's patches were found much inflamed and in two perforation had almost taken place. The uterus and appendages appeared to be normal and no cause for the hæmorrhage could be found. In its early stages the case was an example of ambulatory typhoid fever.

SECRETIN.

IT has been shown that the introduction of acid into the duodenum was productive of secretin even after destruction of all nerve connexions of the pancreas and alimentary canal with the central nervous system and even after extirpation of the sympathetic ganglia of the solar plexus. With a view to determine the mechanisms of this reflex secretion of the pancreas, as well as of the adaptation of the pancreatic secretion to variations in the food of the animal, Mr. W. M. Bayliss, F.R.S., and Dr. E. H. Starling, F.R.S., commenced an interesting research the results of which were communicated to the Royal Society in the Croonian Lecture this year. From a consideration of previous work on the subject these writers surmised that as the introduction of acid into the blood stream had no influence on the pancreas the acid introduced into the intestine must be changed in its passage to the blood-vessels through the epithelial cells or must produce in these cells some substance which on access to the blood stream evoked in the pancreas a secretion. This was found to be the case. On rubbing up the mucous membrane with acid and injecting the mixture into the blood stream a copious secretion of pancreatic juice was produced. It was then found that the active substance, which the writers call "secretin," was produced by the action of acid from a precursor in the mucous membrane, probably in the epithelial cells themselves. Once formed by the action of acid it could be boiled, neutralised, or made alkaline without undergoing destruction. The precursor of the substance (pro-secretin) cannot be extracted by any means that were tried from the mucous membrane. Even after coagulation of the mucous membrane by heat or alcohol secretin can still be extracted from the coagulated mass by the action of warm dilute acid. The writers are inclined to believe that the chemical mechanism described is the only method by which the pancreas is induced to secrete. Secretin can be split off from its precursor in the mucous membrane by the action of acids or boiling water. It is therefore concluded that the process is one of hydrolysis. Secretin is neither a coagulable proteid nor a ferment. It is soluble in 90 per cent. alcohol in the presence of ether but it is insoluble in absolute alcohol and ether. It is slightly diffusible through animal membranes. It can be filtered through a gelatinised Chamberland filter. It is not precipitated by tannic acid, thus excluding bodies of alkaloid nature as well as di-amido compounds. This evidence, slight though it is, points to secretin being a body of relatively small molecular weight and not a colloid. It may be compared to the active principle of the suprarenal glands, adrenalin, which has been obtained in a crystalline form and the chemical constitution of which has been approximately determined. This is, indeed, what would be expected of a substance which has to be turned out into the blood at repeated intervals in order to produce in some distant organ or organs a physiological response proportional to the dose. The discovery of secretin has placed in the hands of physiologists the power of controlling the activity of a gland by purely phy means and Mr. Bayliss and Dr. Starling have taken opportunity of the control thus acquired to investigate the exact character of the changes induced in the pancreas under this physiological stimulus. Apparently, secretin has no specific influence on any one constituent of the pancreatic juice. When injected it causes secretion of a juice which is normal in that it resembles the juice secreted on entry of food into the duodenum, and contains a precursor of trypsin, amylopsin, and steapsin. Secretin, in fact, appears to cause the pancreatic cells to turn out the whole of the mesostates which they have accumulated during rest in preparation for the act of secretion. If secretin be injected at repeated intervals until the gland will no longer respond to the injection it is found on microscopic examination that the cells have discharged the whole of their granules. Under healthy conditions it is probable that the activity of the pancreas is two-fold in character and that the normal stimulus of secretin excites not only a breaking down of the protoplasm and a discharge of granules but also a building up of the protoplasm and a new formation of granules. So marked, in fact, is this power of self-restitution that it is often advisable to diminish the resistance of the animal by bleeding or other means if it is desired to obtain a specimen of exhausted gland. So far the writers have dealt only with the correlation of the activities of the cells lining the intestinal tube with those forming the masses of the pancreas and liver, from which it will be seen that a very large part of this correlation is played by a chemical substance which acts, so to speak, as a chemical messenger between these various organs. A striking feature, however, of the pancreas is its alleged power of adapting its secretion to the nature of the food taken in by the animal. A study of the mechanism by which the pancreas can adapt itself to the nature of the food has been carried out and completed by Dr. F. A. Bainbridge in an interesting series of physiological experiments. It was found that as the result of injecting lactose some substance which may be called *x* is produced in the mucous membrane of the small intestine. This substance is carried by the blood to the pancreas and there slowly gives rise to the formation of lactase which is turned out in the juice when secretion is excited by the entry of acid chyme into the duodenum. As yet the nature of this substance *x* is not known. All that can be said is that it is destroyed at a boiling temperature, since boiled extracts of the mucous membrane of milk-fed dogs do not, when subcutaneously injected, cause the appearance of any lactase in the pancreatic juice of biscuit-fed dogs.

ALCOHOLISM IN SCHOOL CHILDREN.

OUR Berlin correspondent writes: "Dr. Goldfeld, medical officer to the public schools at Schöneberg, a suburb of Berlin, has recently carried out an investigation on the spread of alcoholism in school children. The investigation included a boys' school of 470 and a girls' school of 497 children (a total of 967 children), the result being that not less than 496, or 51·3 per cent., of the children were accustomed to indulge daily in the drinking of beer, whilst 299, or 30·9 per cent., casually took spirits also. The quantity of beer consumed was from one to two glasses of a quarter of a litre a day. Malt beer was preferred by the majority, whilst some drank lager beer, or the so-called white beer, a special Berlin beverage containing a great quantity of carbonic acid and a relatively small quantity of alcohol. As to the other liquors Dr. Goldfeld states that rum, kümmel, cognac, or even a combination of several spirits was taken. As a rule the father on going to a public-house invited his children to go with him, where he allowed them to have a drink. Children of publicans were especially liable to indulge in spirits. It was not only the boys but also the girls who liked to drink beer, but they preferred the sweeter liquors to the sharper ones. The teachers informed Dr. Goldfeld that children accustomed to the use of spirits were especially lazy, absent-minded, and inclined to tell lies. Dr. Goldfeld undertook to warn the children against the danger of alcoholism but without any success, the children continuing to drink. Although his endeavour was supported by the teachers the parents were not to be persuaded and the influence exerted by the school was checked by that of the parents. Dr. Goldfeld proposes that eventually addresses should be read on the subject before a meeting of parents of children attending individual schools and that, moreover, they should be provided on behalf of the school authorities with a short essay dealing with the dangers of alcoholism." The tables given in Dr. Goldfeld's paper show that of 470 boys 264, or 56·2 per cent., daily drank beer and 139, or 30 per cent., were casual drinkers. In one of the classes 96·2 per cent. were regular drinkers and in another only 33⅓ per cent. Spirits were taken by from 17·7 to 60·4 per cent. The figures relating to girls, though sufficiently serious, showed a less prevalent consumption of alcohol.

THE OPERATIVE TREATMENT OF RETROFLEXION OF THE UTERUS WITH ADHESIONS.

THE treatment of cases of retroflexion of the uterus with prolapse of the ovaries and adhesions preventing the reposition of the displaced organs is often a source of great trouble to the practitioner. The distress caused to the patient by such a condition is frequently extreme and yet ordinary methods of treatment may quite fail to give any relief. That most cases of retroflexion giving rise to symptoms where the uterus is moveable and can be replaced should be treated by the introduction of a pessary there can be no question. It cannot be justifiable in such cases to practise any operation if relief can be obtained by a pessary, unless indeed the patient refuses to wear such a support. In cases, however, where a pessary gives no relief and where the patient, as not infrequently happens, is made a chronic invalid by the conditions, the question of operative treatment must be considered, and it is precisely in this class of case that so much difference of opinion exists as to what operation should be performed. Shall the patient be treated by Alexander-Adam's operation, shall the round ligaments be shortened intraperitoneally, or shall the fundus uteri be fixed to the abdominal wall by one or other of the methods of ventrofixation? If adhesions are present then the view taken by most operators is that they can be dealt with most safely and most certainly after opening the abdomen. In such circumstances, then, either ventrofixation or intraperitoneal shortening of the round ligaments must be carried out. Which of these two operations is most likely to be followed by permanent results and lead to no subsequent disability? The question is one that does not admit of a ready answer. That ventrofixation has in some instances given rise to trouble in subsequent confinements there can be no question. But if the lower part of the uterus alone be fixed to the abdominal wall such fixation would not appear at all likely to cause subsequent trouble. On the other hand, the intraperitoneal method of shortening the round ligaments is quite safe from the point of view of any trouble being caused in a future pregnancy, but the permanency of the result is on the whole less certain. Our own feeling in the matter is that while intraperitoneal shortening of the round ligaments is not at all likely to be attended by any subsequent trouble, yet the permanent result of ventrofixation is much more certain. The method of practising it in which the lower uterine segment alone is fastened to the abdominal wall reduces the risk of any trouble at a subsequent pregnancy to so small a factor that this should be the operation of election in all cases of retroflexion of the uterus with adhesions where operative treatment becomes necessary. The problem is a much easier one in the case of patients who are not likely to have any more children either because they are past the menopause or from some other reason. Here the advantages of ventrofixation are not in any way counterbalanced by the risk of trouble in connexion with subsequent pregnancy or labour. For such patients the operation is especially indicated. Its dangers in these days of antiseptic surgery are so small that it may be recommended with confidence both as regards its risk and, if a good method be adopted, as regards the permanency of the cure of the displacement and the relief of the symptoms.

OVERCROWDING IN TRAINS.

WE have more than once referred in the columns of THE LANCET to the overcrowding of railway trains[1] and have pointed out that what is wanted is a combination among the passengers. Efforts are now being made to form this combination. We print in another column a short notice of an important meeting held in London on July 28th to protest against the attitude of certain railway companies towards their passengers and we hope that the movement thus inaugurated will not be allowed to drop. In order to show the urgency of this question of overcrowding on railways it may be interesting to recall to our readers' memory a few points made in a paper read at the Royal Statistical Society on March 15th, 1904, by Mr. E. J. Harper, statistical officer to the London County Council. Mr. Harper showed that during 1902 the local and other railways serving Greater London carried the enormous total of 600,000,000 passengers, the railways covered a little under 600 miles, and the London area was served by 531 stations. The lines which carried the greatest number of people per annum were the Metropolitan, which carried over 95,000,000, the District, nearly 49,000,000, the North London, over 50,000,000, the "Twopenny Tube," over 45,000,000, and the City and South London, nearly 20,000,000. From 3 to 10.30 in the morning the number of passengers brought into London from the suburbs was 410,471 and the greatest percentage of overcrowding on a single train was 72·1 per cent. This train carried a fraction over 17 persons in each ten-seated compartment. How it affects workmen may be inferred from a Parliamentary Blue-book issued in February of this year by which it appeared that the number of workmen's tickets issued on all railways within the metropolitan area in 1902 was nearly 62,000,000. There seems to be a general opinion abroad that when the lines of some of the chief offending railways are "electrified" overcrowding will disappear, but it must not be forgotten that although the managers of those railways will be granting increased facilities they have stated that they expect a large access of traffic, and how far that increase of traffic will counterbalance or outweigh the new facilities remains to be seen. It is possible that the general public may be too optimistic as to the good results which will arise from "electrification." At all events, the remarks of Lord Claud Hamilton, the chairman of the Great Eastern Railway Company, at the half-yearly meeting of the company held in January, 1904, give food for thought. He compared that railway with two specimens of the electric system—viz., the Central London and the Manhattan Railway of New York—and claimed that his railway was able to provide in the busiest period about twice as many seats as either of these two electric railways. The great difficulty of some of the railway companies appears to be that not all the platforms are long enough to allow of increasing the number of coaches per train. Some of the railway managers complain that the great cause of overcrowding is that the majority of people travel by the latest train that will convey them to their business in time and therefore rush up at the last moment. Sometimes, however, the railway companies "cut out" a certain train in the busy time when the passengers who usually travel by it have to travel by, and grossly overcrowd, the next train. Again, sometimes a train is delayed at a busy station and the barriers are not shut, with the consequence that passengers crowd into the already full carriages. These, however, are episodes on which no stress need be laid; what must be remedied is the regular and serious overcrowding of most of the trains running in and out of London at the busy times of the day.

THE DEVELOPMENT OF NERVE FIBRES.

SOME recent statements made by Dohrn and Bethe to the effect that ganglionic nerve cells play no part in the formation of nerve fibres have met with vigorous opposition from the veteran histologist Kölliker who in an article contributed to the *Anatomischer Anzeiger* strongly supports the doctrine long ago enunciated by himself and greatly strengthened by the observations of Ramon y Cajal. Whilst Dohrn and Bethe contend that nerve fibres develop independently of the cells from the fusion of ectodermic cells which subsequently constitute the so-called Schwann's cells, Professor Kölliker is perfectly convinced that all nerve fibres of vertebrata are *primarily processes of the protoplasm* of either peripheral or central nerve cells, in every case the nerve cells sending forth one process, and one only, whilst every nerve fibre terminates in a free extremity. He points out that the nerves of the spinal cord and medulla oblongata originate in the nerve cells and that subsequently the protoplasm of the process becomes differentiated into axis cylinder and medullary sheath. The axis cylinder afterwards becomes surrounded by small cells and terminates in the mode described by Cajal in ramifications which embrace other cells. The peripheral motor and sensory fibres become surrounded by special cells which form an investment to the ganglion cells and form also the sheaths of Schwann. All these cells proceed from the mesoderm and increase in number by mitosis.

RADIUM ENERGISED WOOL: RUSSIAN EXPERIMENTS.

IN a review by Mr. Elpe in the *Novoe Vremya* on the progress of recent inquiries into the properties of radium it is stated that Dr. E S. London of Russia has been studying the question of radium emanations and his investigations lead to the conclusion that generally radium emanations do not differ in their physiologo-pathological action from the action of radium itself. Both inflame the skin and are destructive to various kinds of life. Dr. London carried out a series of tests with widely differing subjects, such as paraffin, cork, paper, and cotton-wool, which were subjected for some time to radium emanations and produced inflammatory effects on the skin, the most intense radio-activity being observed in the case of the wool which because of its sponginess absorbs a large quantity of radium emanations. This inclines Dr. London, in respect of treating skin diseases with radium, to pay particular attention to this faculty of wool. "Emanated" wool, according to him, offers, in the first place, the facility of easy distribution over the body and it can be conveniently adjusted to any part according to the needs of the case. In the second place, in the vehicle of wool radium becomes conveniently portable and radio-active energy, as in charged wool, can be sent great distances, since in hermetically

closed vess [illegible]
the same time radio-active wool may become part of pharmaceutical stock and at no great expense, for from five to ten milligrammes of radium are sufficient to energise a large quantity of wool. However, as to this Dr. London is careful to state that before making "emanated" wool an article of pharmaceutical commerce we must know how and in what particular cases the commodity would be useful—and that is still a question for the future.

TREATMENT OF PERTUSSIS BY VACCINATION WITH CALF-LYMPH.

WE have received from a correspondent the records of five cases of pertussis in which recovery ensued when the patients were vaccinated with calf lymph in the usual way as a protection against small-pox. The diagnosis in each case was undoubted and no other treatment was employed. The symptoms of pertussis abated when the vesicles matured and the cough had entirely gone in about 11 days. The suggestion that one pathogenic organism might destroy another has been occasionally raised, but so far as we are aware no definite proof of this antagonism has been brought forward. "Mixed infections" are not uncommon and in some cases the action of a pathogenic organism has been rendered more intense by the injection of a non-pathogenic microbe but we are not acquainted with any trustworthy investigations which tend to show that one germ can act as an antidote to another. Our correspondent is naturally much impressed with the result of vaccination in his cases but admits that the question still remains as to whether vaccinia virus is a specific in such cases or whether any form of absorption from a local infective centre would have a similar result. We agree with him that it would be interesting to ascertain whether other practitioners have had a similar experience.

DAKHYL *v.* LABOUCHERE.

IN this case a new trial has been ordered by the Court of Appeal and it is therefore again *sub judice.* In the circumstances it will be sufficient to explain briefly the reasons why it has to be re-heard and to await with interest the verdict of a second jury. The plaintiff, it will be remembered, was a person possessing foreign qualifications only and practising medicine in London, either chiefly or entirely in connexion with cases of deafness. He had been, but had ceased to be, medical adviser at the Drouet Institute when there appeared in Mr. Labouchere's paper an article criticising him adversely, the sting of the alleged libel lying in the term applied to him, "a quack of the rankest species," it being further stated that he had "left the Drouet gang in order to carry on a 'practice' of the same class on his own account." The principal misdirection of the jury by Lord Alverstone upon which the Court of Appeal based its order for a new trial consisted in directions which amounted to a finding by his lordship that the words used were libellous, instead of the question whether they were so or not being left to the jury. The question of "libel or no libel" is essentially one for the jury, the judge being limited to a decision if necessary as to whether the words complained of are *capable* of being a libel. The summing up of Lord Alverstone, however, was such that the jury might have inferred that to call a person possessing medical qualifications a "quack" was necessarily a libel upon him, whereas the Master of the Rolls pointed out, what indeed is obvious, that a man may be fully qualified to practise medicine and yet may be fitly called a "quack" should he resort to "quack" methods. The definition of a "quack," apparently accepted in this case as "a boastful obviously permits the term to be applied with justice to a person qualified by education and registration to practise medicine, if only because such an one may claim the power to remedy conditions which are irremediable. It was also held by the Court of Appeal that the learned Lord Chief Justice had not properly left to the jury the question whether the words used were or were not "fair comment upon a matter of public interest," because in summing up he had sought to distinguish between comment on the plaintiff and comment upon the Drouet Institute. The question whether the matter was of "public interest" was for the judge to decide but the question whether the criticism was "fair comment" was for the jury. Referring to the criticism of the plaintiff in his connexion with the Drouet Institute the Master of the Rolls said that if the writer "commented upon the methods of the person who worked the institution and said that the person was working a quack institution and was therefore himself a quack it would be for the jury to say whether the comment was fair comment or not." The Court of Appeal therefore ordered a new trial, the costs of which will include those of the first one and of the appeal, but, of course, this was done without any intimation or suggestion as to what, in the opinion of the Court, the result of such new trial should be.

IN the House of Commons on August 3rd Mr. T. Chamberlayne asked the Home Secretary whether he would consider the advisability of imposing some restrictions on the advertising of patent medicines with a view to protecting persons of the poorer classes. Mr. Akers-Douglas replied that the question of legislation for the purpose of dealing with certain evils in this connexion had been considered in his department, but he spoke as though he were much oppressed with the difficulty of doing anything.

Dr. Frederick John Hicks, who was charged at the Central Criminal Court with performing an illegal operation upon a young married woman, was found not guilty.

THE King has appointed Sir William MacGregor, K.C.M.G., C.B. (Governor of Lagos), to be Governor and Commander-in-Chief of the Island of Newfoundland and its Dependencies.

THE REPORT OF THE PRIVY COUNCIL UPON PHYSICAL DETERIORATION.

IN September last a Committee of the Privy Council was appointed by the Duke of Devonshire, at that time Lord President of the Council, to investigate the subject of physical deterioration as affecting the British population. The committee consisted of the following members: Mr. Almeric FitzRoy, C.V.O., clerk to the Privy Council; Colonel G. M. Fox, C.B., formerly head of the Army Gymnastic School; Mr. J. G. Legge, chief inspector of reformatory and industrial schools; Mr. H. M. Lindsell, C.B., assistant secretary to the Board of Education; Colonel G. T. Onslow, C.B., inspector of marine recruiting; and Dr. John Tatham of the General Register Office, Somerset House. The terms of the first reference were as follows: "To make a preliminary inquiry into the allegations concerning the deterioration of certain classes of the population as shown by the large percentage of rejections for physical causes of recruits for the army and by other evidence, especially the report of the Commission on Physical Instruction in Scotland; and to consider in what manner the medical profession can best be consulted on the subject with a view to the appointment of a Royal Commission and the terms of reference to such a commission if appointed." Shortly afterwards this reference being found unsatisfactory was enlarged and the committee was further instructed "(1) To determine with the aid of such counsel as the medical profession are able to give the steps that should be taken to furnish the Government and the nation at large with periodical data for an accurate comparative estimate of the health and physique of the people (2) to indicate generally the causes [illegible] ation as does exist in certain [illegible] ; the means by which it can m[illegible]

The committee has been commendably assiduous in the conduct of its inquiry for within a period of less than 11 months from the date of its appointment it has examined 68 witnesses carefully selected from each division of the kingdom and after the fullest deliberation, involving a lengthy correspondence it has unanimously agreed to its report which has been duly presented to Parliament. There are many competent persons who entertain the opinion that a matter of supreme public importance like the present, involving a critical examination of the state of the national health should have been referred not merely to a departmental committee but to a Royal Commission fully equipped with power to require the attendance of witnesses the production of documents, and so on, and with such other prerogatives as are conferred on commissions of that type. *But after careful study of the report before us* which has been prepared by a committee of seven members of the Civil Service, we think that the public will approve of the committee's conclusions although the body arriving at them may be destitute of the authority, independence and prestige which the King's mandate implies. Whether or not the recommendations are carried into effect by the Government or by the several minor authorities concerned We have no hesitation in saying that the committee has done most useful work.

For the convenience of our readers we may here briefly recapitulate the circumstances which led to the present investigation. In the *Contemporary Review* for January, 1903 Major General Sir Frederick Maurice published an article which, without disputing its interest and suggestiveness may be called sensational entitled The National Health a Soldier's Study. This article, which constituted a serious impeachment of the health of the British nation was based on the personal observations of Sir Frederick Maurice himself and of the then Inspector General of Recruiting with respect to the physical character of the youths who present themselves as recruits for the British army. The *fact relied on to justify this impeachment* was that according to recent experience, out of every five men offering themselves for enlistment only two are to be found in the army as effective soldiers by the end of two years service. Shortly after the appearance of this article the Director General of the Army Medical Department addressed a memorandum to the Secretary of State for War drawing attention to the writings of Sir Frederick Maurice and sharing with that officer responsibility for the statement that a very large proportion of the men who offer themselves for enlistment into the army are found to be physically unfit for military service. The intricacies of War Office administration have always been a sealed book to outsiders nor is it generally known to what extent the official chiefs of the various departments are expected to atone for the shortcomings of other branches of the service. But without prying into official secrets we have it on high authority that the method adopted by the Director General of the Army Medical Department is strictly in accordance with official precedent. In a letter published in THE LANCET of Feb 7th 1903, p 397 Surgeon Colonel F H Welch A M S, tells us that several years ago Sir Thomas Crawford late Director General of the Army Medical Department, finding that the material then available for recruiting had fallen lamentably short of the ideal published a paper based on army statistics in which he deduced conclusions practically identical with those for which we are indebted to Sir Frederick Maurice and the present Director General of the Army Medical Department. In a leading article in THE LANCET of Jan 31st, 1903, p 315, we ventured to challenge the validity of Sir Frederick Maurice's conclusions. We endeavoured to show that the health statistics of the class of men desiring to enlist in the army are by no means those of the general people but are rather the health statistics of that part of the population which the late Inspector General of Recruiting has described as "very largely rubbish."[1] If this be so it is unjust and absurd to disparage the health of the entire British nation on the strength of data relating exclusively to a comparatively small part of it.

On the issue as a Parliamentary paper of Sir William Taylor's memo [illegible] War the controvers [illegible] n of the masses rep [illegible] publication of that [illegible] has been flooded w [illegible] ation in physique of the labouring classes, while the usual crop of silly and impracticable suggestions has followed for the abatement of an evil the existence of which has been accepted without question. Early in July of last year the Earl of Meath drew attention to the subject in the House of Lords, basing his remarks on a statement in a report of the Inspector General of Recruiting for 1902 which once more affirmed the existence of deterioration among the classes furnishing army recruits. His lordship was followed by the Bishop of Ripon who, whilst personally sceptical as to the extent of the mischief alleged to exist advocated full inquiry into the matter. Upon this the Lord President of the Privy Council undertook to take the opinion of the Royal Colleges of Physicians of London and Surgeons of England on the entire subject and this we now know to have been in favour of further inquiry. On Sept 2nd the Duke of Devonshire announced the appointment of the committee which has recently made its report.

For convenience of comment upon the different matters of reference the committee has distributed the subject matter of its report under three headings. The first deals with the War Office memoranda, the second discusses the causes of such degeneracy as is known to exist together with the appropriate means for its amendment, and the third contains a summary of the principal recommendations of the committee. Under these headings severally, and in the same order, we propose to summarise the chief points in the committee's report. In pursuance of the scheme of procedure dictated by the terms of its reference the earliest evidence invited by the committee was that of Sir William Taylor, Director General of the Army Medical Service and that of the late Inspector-General of Recruiting, General Borrett. Major-General Sir Frederick Maurice also gave evidence on the same day. The reports and memoranda issued by the War Office on the responsibility of the first two officers above mentioned were naturally the first to engage the committee's attention. These documents having been formally submitted to the judgment of the two Royal Colleges the committee very properly prefaces its report with a statement of the [illegible] authorities which was [illegible] (1) that the evidence [illegible] memorandum is inadequate to prove that physical deterioration has affected the classes referred to, (2) that no sufficient material (statistical or other) is at present available to warrant any definite conclusions on the question of the physique of the people by comparison with data obtained in past times, and (3) that a partial investigation, as for instance, into the conditions of the classes from which recruits are at present mostly drawn, might be misleading and might give rise to erroneous conclusions on the general question. The Royal College of Physicians of London however differed from the sister College in Lincoln's Inn Fields by advocating an inquiry into the present physical condition of the people—an expedient which the latter authority did not think necessary. With regard to the War Office memorandum, the committee remarks that an independent examination of the Director General's papers undertaken by the authorities of the Metropolitan Police has led *to the conclusion* that the calling of a soldier has ceased to attract the class of men who formerly enlisted, and as a consequence a large proportion of the "residuum" of the population come under the notice of the army recruiting authorities. This conclusion appears to be borne out by the complaints of commanding officers as to the physique of many of those enlisted and tends to explain the drain from desertion among those who find themselves disappointed in the hopes of an easy existence. Again, Professor Cunningham of Edinburgh criticises the value of the War Office figures thus "Perhaps the most unreliable evidence," he says, "is that which is obtained from the recruiting statistics because the class from which the recruits are derived varies from time to time with the conditions of the labour market. When trade is good and employment plentiful it is only from the lowest stratum of the people that the army receives its supply of men; when, on the other hand, trade is bad a better class of recruit is available. Consequently the records of the recruiting department of the army do not deal with a homogeneous sample of the people taken from one distinct class." In one respect especially the data supplied by the War Office are unsatisfactory. On p. 2 of the Director-General's memorandum it is stated that three-fifths of the recruits examined come under Class I. of the Army official tables, which class consists of "labourers, servants, husbandmen, &c." On reference to the census returns we find that this description does not tally with any classification hitherto adopted for enumeration purposes; therefore, as the health and physical condition of street loafers, costermongers, and dock labourers differ widely from those of agricultural labourers, all of which workers are nevertheless included in this category, it follows that no useful analysis can be made of that very class of the population from which our army recruits are for the most part derived.

---

[1] Report of Committee on Physical Deterioration par 25.

In the course of their evidence both the Director-General and the late Inspector-General of Recruiting were fain to admit, on being pressed, that the real lesson of the recruiting figures was the failure of the army, under present conditions, to attract a good type of recruit. Indeed, General Borrett gives up the case for widespread deterioration when he says: "It is a pity that the physique of the recruit-giving class is as poor as it is, so as to cause such a large percentage of rejections for the army." And again, when in answer to a question whether "the men who want to be soldiers" were not those people who have no opening in life or have no occupation, and who drift to the recruiter in the vague hope of being passed, he replies, "There are a great many of that kind, no doubt; I must confess that a great many are that way." Moreover, Sir William Taylor could not deny that, even if the number rejected by the recruiters was as large as some people suppose, it might merely imply that a great many not fit or disinclined for permanent work present themselves to the recruiting sergeant on the chance of being passed, and that the condition of those rejected is only representative of the state of the wastrels of the large towns who live by casual labour. As another and very excellent witness, Dr. A. Eichholz, observed: "It is the years after leaving school that determine so many lives; by the time the boy has reached 17 he has shown either self-improvement or self-deterioration, in which last case you may get him for a soldier. At 17," he goes on to say, "you are landed with the failures and the lack of self-improvement which they have exhibited is largely bound up with their physical condition. At 17 they become street loafers, practically the only available source of recruiting for the army." The committee quotes the following vivid description of these persons from Mr. Charles Booth: "These men hang about for the 'odd hour,' or work one day in the seven; they live on stimulants and tobacco, varied with bread and tea and salt fish. Their passion is gambling. Sections of them are hereditary casuals; a large portion of them drift from other trades; they have a constitutional hatred to regularity and forethought and a need for paltry excitement. They are late risers, sharp-witted talkers, and, above all, they have that agreeable tolerance for their own and each other's vices which seems characteristic of a purely leisure class, whether it lies at the top or bottom of society." The evidence of Sir Frederick Maurice did not modify the impression produced by that of either the Director-General or the late Inspector-General of Recruiting, nor could the committee accept the basis of the somewhat alarmist statement for which he is responsible—namely, that of those who wish to be soldiers only two out of five are to be found in the ranks at the end of two years. Sir Frederick Maurice obtains this result by taking the 34·6 per cent. of rejections by medical examiners and the 2·1 per cent. of those discharged before the completion of two years, and adding thereto a purely conjectural percentage as to the number of those previously rejected by the recruiters. It was stated by Sir William Taylor that no record whatever of these latter was preserved, but the committee thinks that if such a record could be maintained it might be useful to dispel false impressions as to the actual number. Looking, however, to the condition of the classes from which, as it has been seen, these people issue, the committee does not think that the proportion, even if it were as stated by Sir Frederick Maurice, is so very disquieting; indeed, a very competent medical witness, Dr. Eichholz, takes the view that having regard to the circumstances in which the British army is recruited the fact that 40 per cent. of those that present themselves to the recruiting officers become good soldiers is more to the credit of the physique of the people than the fact that under the German system of conscription only 16 per cent. of those liable to serve are rejected. From what has here been said we are by no means surprised to hear that, in the words of the report, the examination of the official representatives of the recruiting system has left upon the minds of the committee the conviction, confirmed as it has been by the evidence of other witnesses, that it would be as reasonable to argue from criminal statistics to the morals of the great mass of the people as it would be to argue to their physical condition from the feeble specimens which come under the notice of recruiting officers.

(To be continued.)

Looking Back.

FROM

THE LANCET, *SATURDAY*, AUGUST 5, 1826.

Electricity you are aware has been used in amaurosis, as well as in most other nervous affections. Mr. Hey, of Leeds, published some cases of amaurosis which he considered much benefited by the use of electricity; and the late Mr. Ware seems to have relied on it almost entirely. Indeed this influence in all the varieties of its application, and various other stimulants, have been tried over and over again in this affection; I have seen no benefit from it.

The tonic and stimulating plan of treatment has always been, and is still mentioned in the treatment of amaurosis. If I were to enumerate all the remedies of this class, which have been recommended and actually used, I should have to recount everything that comes under the head of tonic and stimulant, of nervous, antispasmodic, and antiparalytic. The greatest favourites, however, have been the arnica montana, pulsatilla, valerian, black hellebore, calamus aromaticus, camphor, opium, hyoscyamus, musk, castoreum, phosphorus, ammonia, flores zinci, steel, and naphtha; even fried millepedes have been strongly recommended.[1]

FOREIGN DEPARTMENT

MATERIA MEDICA.

M. Robinet on Mustard.—(Idem.)[2]

This distinguished chemist has discovered, that in pressing the mustard seed even in the cold, there can be obtained 20 per cent. of a fixed oil, having little smell and no vesicating power, while the residue deprived of this oil, becomes sharper and more blistering.

Hence the powder deprived of this oil would be much more active in cases where sinapisms are necessary.

[1] Excerpt from Lecture on the Anatomy, Physiology, and Diseases of the Eye, delivered by Mr. Lawrence in the London Ophthalmic Infirmary, Moorfields.

[2] "Journal de Physiologie, par F. Magendie, bearing date April 1826, but only just published."

RUSSIAN PRECAUTIONS AGAINST CHOLERA.—The Medical Department of the Caucasus has, says the *Novoe Vremya*, ordered the disinfection of all letters and parcels coming from Persia. The Discount and Loan Bank of Persia (which is a branch of the Russian Imperial Bank) has fitted out three sanitary bacteriological sections to combat the spread of cholera from Persia into Russia. Each section consists of a medical man, a lady doctor, assistants, and sanitary officers, and they are furnished with travelling bacteriological laboratories and a stock of disinfectants and drugs. The Institute of Experimental Medicine organised these bodies which have left St. Petersburg for their work, the bank named bearing all expenses.

THE BRITISH MEDICAL ASSOCIATION.

MEETING AT OXFORD

THE meeting of the Association came to an end on Friday, when there was a general exodus from Oxford

On Wednesday evening a conversazione was given by the Vice Chancellor and the members of the University at the Museum It was very largely attended and a number of interesting demonstrations were given Prominent among these were the demonstrations by Mr C E Walker and by Dr W Ford Robertson on researches connected with cancer Dr W Ramsden also repeated his beautiful experiments upon bubbles and surface films which he showed at the Royal Society's conversazione on June 19th, 1903 The enjoyment of the evening was somewhat marred by torrents of rain which began to fall about 10 30 and there was a woeful scarcity of cabs The weather also affected the astronomical demonstrations which had been arranged in the Observatory for the only thing to be seen through the telescope was the spider web cross lines However, the sight of these seemed to afford great pleasure to a number of people

The annual dinner of the Association was held on July 28th in the hall of Christ Church The company numbered about 300 and the Very Rev the Dean of Christ Church (the Rev T B Strong, D D) was in the chair Amongst those present were the Vice Chancellor of the University (Dr D B Monro), the President of the British Medical Association (Dr W Collier), the Rector of Lincoln, the President of Magdalen, the Warden of Wadham, the Senior and Junior Proctors Sir John Moore, Dr T D Acland, and Sir W Macewen After the usual loyal toasts had been duly honoured the Warden of Wadham submitted ' The Imperial Forces, which was acknowledged by Surgeon General G J H Evatt, C B The toast of The British Medical Association was entrusted to the Rector of Lincoln He gained the sympathy of his audience by dwelling on the great progress that had taken place in the medical profession since the Association was started 72 years ago Mr Andrew Clark, chairman of the council of the Association in his response to this toast said the number of members had increased under the new constitution and laws Sir John Moore then proposed "The University and City of Oxford, and this was acknowledged by the Vice Chancellor and by the Mayor Sir W Macewen then submitted The President and the Executive of the Oxford Division of the Association, and the President of the Association in reply, stated how Sir John Burdon Sanderson had declined the honour of taking the office of President because of ill health He concluded by proposing the toast of "The Guests, ' to which Professor Osler replied The last toast of the evening was The Governing Body of Christ Church, given by Dr Acland and this having been suitably responded to by the Dean concluded the proceedings of the evening

The thirty fifth annual medical temperance breakfast given by the National Temperance League was held in the Town Hall Oxford, on July 28th Mr W McAdam Eccles presided over the gathering of 240 guests—the largest number that have ever been present Among those who supported him were Sir Victor Horsley, Sir John Moore, Dr J J Ridge, Dr T B Hyslop, Dr Robert Jones, Dr W Odell, Dr Heywood Smith, Surgeon General Evatt, C B , Colonel T H Hendley, C I E , Dr G E Shuttleworth, Dr T D Savill, Professor Murdoch Cameron, Mr R Henslowe Wellington, and Mr W Soltau Eccles The Chairman in a brief address remarked that the profession moved cautiously in the matter of alcohol but was earnestly alive to its important responsibility The public, he said, still needs informing that alcohol is not an absolute necessity for the human frame and medical practitioners must undertake their part in this work of tuition He strongly advocated some means of systematic instruction of medical students in the question of the use and abuse of alcohol Dr Collier said he was a strong supporter of moderation in the use of alcohol and wished to urge upon all members of the staffs of hospitals the utmost care in the prescription of alcohol, seeing that patients were so apt to take the exhibition of alcohol in the wards as an indication that they should continue to take it after discharge In his own wards at the Radcliffe Infirmary extremely little was given Dr T N Kelynack delivered an address on the Present Position of the British Medical Profession in Relation to Alcohol, reviewing the rise of the scientific study of alcoholism and the practice of the profession in the past as to its prescription in disease He then turned to the results of experiment and pointed out that the biologist had shown that the physical basis of life in both the animal and vegetable kingdoms may be detrimentally affected by alcohol As regards the present-day practice of the profession while it may rightly have been urged in the past that there was an unwarrantable laxness in the use of alcohol, every well informed practitioner is now fully alive to his responsibility in the matter He was sure that what was proved to be scientifically right cannot be ethically wrong A vote of thanks to the league was proposed by Dr Odell and responded to by Dr G Murray, the philologist of Oxford who had for long been a Vice President of the league A vote of thanks to the chairman was proposed by Dr Robert Jones of Claybury and Mr Eccles briefly responded

On Thursday evening, besides the annual dinner of the Association, a reception was given by Mrs Collier and the ladies of the reception committee, at which the members of the Association were entertained at a party in New College Gardens The weather was beautiful and the gardens were illuminated in the best possible taste with "fairy lamps" and Japanese lanterns The moon was full or nearly so and the gardens, bounded as they are by the old city walls, looked their very best The band of the Royal Marines played a selection of good music with their well known skill, and in the hall Mr A M Heathcote recited various dramatic sketches

At an earlier hour the same evening Dr G Bagot Ferguson gave a popular lecture in the schools on Disease Germs This is the first occasion upon which a popular lecture has been given under the auspices of the Association Mr Councillor Druce, chairman of the sanitary committee, was in the chair and after a few introductory remarks he called upon Dr Ferguson to give his lecture Dr Ferguson commenced by giving a short description of micro organisms and pointed out that not all were harmful but that some were of great value He referred to the enormous rapidity with which micro organisms multiply and concluded by some very practical remarks upon hygiene and hygienic methods The lecture was illustrated by lantern slides about 170 being shown

On Friday garden parties were arranged at Worcester College Gardens and Blenheim Palace, the invitations to the latter being sent out privately by the Duke of Marlborough Friday was a terribly wet day and the weather spoiled both functions In the evening the Mayor and Mayoress of Oxford gave a reception at the Town Hall, when upwards of a thousand guests were present. During the evening Dr. Arthur Haydon played the following violin solos: "Legende" (Wieniawski), "Berceuse" (Godard), and "Mazur" (Mlynarski). He gave an accurate rendering of them all, with good intonation, and was well received by the audience.

On the invitation of the mayor and corporation of Leamington Spa the members of the Association proceeded on July 30th to visit the Royal Pump Room and Baths at Leamington, where they were received by Alderman and Mrs. Flavel, the Mayor and Mayoress. The members of the reception committee, assisted by the members of the medical profession in Leamington, acted as guides to the visitors and much interest was taken in the parks and pleasure grounds and other objects of interest in the town. The Warnford Hospital was also thrown open for inspection. The visitors, numbering over 300, were provided with lunch, which was really a sumptuous banquet, at the Town Hall where the chair was taken by the Right Hon. A. Lyttelton, the Secretary of State for the Colonies and M.P. for Warwick and Leamington, who, in proposing the Royal toasts, referred to the great anxiety which prevailed in regard to the foreign relations of this country. Mr. Lyttelton also gave the toast of "The British Medical Association" and rendered a high tribute to the work that the medical profession was doing in tropical climates, instancing the remarkable reduction in malarious fever cases which had recently taken place at Suez. He had also quite lately received reports from the Gold Coast, Sierra Leone, and Lagos, which showed a tendency to the same good results in those places. Dr. Collier, in responding to the toast, gave some interesting details of the extent to which the British Medical Association had spread its organisation over the British Empire. After luncheon the guests repaired in conveyances to Warwick where they were shown over the castle and grounds and entertained to afternoon tea by the Countess of Warwick. A drenching rain somewhat marred the pleasure of the return drive to Leamington where an illuminated concert took place in the Jephson Gardens in the evening.

THE ADJOURNED GENERAL MEETING.

The adjourned general meeting was held on July 29th at the Reception Rooms in the Examination Hall, when Dr. W. COLLIER, the President, announced that an invitation had been received by the Council to hold the Annual Meeting next year at Leicester, which had been accepted. He then nominated amid applause Mr. G. C. Franklin, of Leicester, as President-elect.

THE SECTIONS.

MEDICINE.

WEDNESDAY, JULY 27TH.

Dr. DAVID NEWMAN (Glasgow) referred to a valuable series of 26 cases of

Renal Disease

in which the urinary signs were associated with pain in the kidney and in which nephrectomy had been performed, the capsule and the congested kidney being incised. In a large proportion both the pain and the albuminuria had been relieved, these symptoms having ultimately disappeared in 11 cases. It was important in such cases to decide whether one or both kidneys were the source of the albumin and tube casts by catheterising the ureters and by cystoscopic examination of the orifice of the ureters. He advocated venesection for uræmia and described a special method of his own for the relief of œdema by acupuncture.

Dr. W. RINGROSE GORE (Whitchurch, Salop) discussed the various causes of nephritis from the point of view of treatment.

Dr. SAMUEL WEST (London) read a paper on

A Disseminated Form of Croupous Pneumonia in Children, or primary broncho-pneumonia, in which he differentiated two forms of broncho-pneumonia as occurring in children. One of these varieties corresponded to the form usually described in text-books and the other was similar in its clinical course and temperature curve to the croupous pneumonia of adults but anatomically consisted of disseminated foci of hepatisation.

Dr. THOMAS MCCRAE (Baltimore) read a paper entitled

Acute Lymphatic Leukæmia, with the Report of Five Cases.

The features of the five cases were described. All were males. The ages varied from three to 21 years and the duration varied from 13 days to eight weeks. The average blood count showed hæmoglobin, 35 per cent.; red cells 1800; and leucocytes, 104,000 per cubic millimetre. In every case the lymphocytes were over 90 per cent. of the total leucocytes. An unusual point was that in three of the cases the prevailing type of white corpuscle was the small lymphocyte. The cases in literature were discussed and the very common severe anæmia was dwelt upon as suggesting that it might be better to consider that the changes in the red cells were as important as those in the leucocytes in acute lymphatic leukæmia. Considerable importance was to be attached to the changes in the bone marrow, especially in the cases without glandular enlargement, as helping to fix the seat of the essential changes in the disease. In regard to the etiology the condition suggested a severe toxæmia but the essential cause had yet to be found.

Mr. H. G. ARMSTRONG (Wellington College) read a paper on

Functional Albuminuria.

This symptom occurred in males of from 15 to 25 years of age. Two types of cases were met with—the florid subject with high tension, and the pale, flabby subject with low tension. A neurotic family history was usually present. The symptoms associated with functional albuminuria were apathy and disinclination for work, fainting attacks, and cardio-vascular instability. The symptoms were influenced by posture and readily disappeared on resting. As regarded treatment it was a mistake to prevent the patient from taking exercise; only long distance running and hard rowing should be prohibited. Tonics were indicated in the flabby anæmic cases. The prognosis was very favourable except where the mistake was made of putting the patient to bed on milk diet. A ready method of bedside testing of the urine with tablets of salicyl-sulphonic acid (one grain) was recommended.

THURSDAY, JULY 28TH.

The Treatment of Tuberculous Pleural Effusion and Pneumothorax.

Professor WILLIAM OSLER (Baltimore) opened a discussion on the above subject, remarking, in the first place, that there were three forms of pleural effusion—the pyogenic, the pneumonic, and the tuberculous. The large majority of cases were tuberculous. In the absence of pneumonia or of sepsis a case of pleural effusion was to be regarded with suspicion as tuberculous. He referred to a case of acute pleural effusion occurring in a girl, aged 14 years, who had aortic and mitral valvular disease, with fatal termination; the necropsy revealed a tuberculous pleurisy. Among 176 cases of pleural effusion 30 per cent. of those who could be traced two years after the attack had died from tuberculosis. As aids in diagnosis he considered the study of the exudate and of the sputum and the tuberculin test. In tuberculous effusions the cellular elements of the fluid belonged chiefly to the variety of lymphocytes, in contradistinction to the polynuclear granular cells found in effusions of septic origin. Out of 195 cases of pleural effusion without any definite history or sign of pulmonary tuberculosis in 30 cases tubercle bacilli had been found in the sputum. Certain clinical features pointing to a tuberculous effusion were an insidious onset, early thickening of the pleura, and early retraction of the affected side. For discussion three points were suggested: (1) the importance of early and repeated aspiration, used as the chief means of treatment and not merely as an adjunct; (2) the question whether drugs were of any use; and (3) the necessity of careful after-treatment, both local and general, in every case of tuberculous pleurisy. As regarded the first point it had been taught in the past that aspiration need not be performed until symptoms became urgent, one side of the chest was full, or a moderate-sized effusion had lasted without signs of diminution for several weeks. Professor Osler referred to a paper by Dr. Delafield of New York, published in the *American Journal of the Medical Sciences*, [illegible] removal [illegible] the form [illegible] thorax w[illegible] incision [illegible] est met) [illegible] iodide [illegible] were still employed by many, but he did [illegible] to bed the patient should begin by blowing water from one bottle to another. Deep breathing exercises should be continued for a long time after the attack of pleurisy and the open-air treatment suitable to all forms of tuberculosis should be carried out. Professor Osler demonstrated a useful breathing exercise which expanded the affected side of the chest to its full extent, the other side remaining practically rigid. The treatment of pneumothorax was not considered very hopeful, as 67 per cent. of 49 cases had died. Three groups of cases had to be considered: (1) the traumatic, the spontaneous, those following abscess or gangrene, and some tuberculous cases required no treatment at all; (2) some cases of acute pneumothorax with urgent symptoms demanded immediate operation, and a smaller number of cases *of suppurative pneumothorax required free opening of the* chest in order to convert a valvular into an open pneumothorax; and (3) a few of the cases of pyo- and sero-pneumothorax might be treated as West had urged, by radical operation as in empyema.

Dr. **G. A. GIBSON** (Edinburgh) said that there was room for discussion on the difficulty of diagnosing a tuberculous pleurisy from effusion due to other causes. Examination of the urine often aided the diagnosis in these cases. In many cases he had found the diplococcus of rheumatism in the urine *and he was of opinion that the urine* should be examined in all cases of pleurisy because serous pleural effusion of rheumatic origin often occurred. With regard to treatment, the value of repeated tapping was not to be overestimated and he had found tuberculin useful in some cases. Carefully graduated physical exercises should always be ordered after apparent cure of pleural effusion. In his experience when pneumothorax occurred suddenly, due to muscular or other strain, in subjects of robust health, recovery was usually complete.

Mr. **STANLEY BOYD** (London) said that operation was demanded always in acute cases. He suggested that when tapping became necessary more and more frequently in cases of chronic pneumothorax it might be advisable to drain the cavity slowly by means of fine cannulæ. The lung would thus have a chance of rest but he admitted there was a danger of setting up pyopneumothorax by such a mode of treatment. He described several cases of pyopneumothorax in which he had operated, removing large portions of the ribs; the results had not been encouraging, five out of six having died.

Dr. **SAMUEL WEST** (London) considered that the term "rheumatic pleurisy" as usually employed was misleading and should be limited to cases due to the diplococcus of rheumatism. He agreed as to the importance of aspiration. Pleural effusions rarely changed their character—serous remained serous, as a rule, but a serous might be converted into a purulent effusion by septic instruments. Aspiration was a dangerous operation as often performed; pneumothorax, cough, and respiratory embarrassment were a few of the complications of unduly rapid exhaustion by aspiration. Empyema, even of tuberculous origin, should be treated as were other forms of empyema, by incising the chest wall freely and washing out the cavity. The ribs should not be excised. If drainage by a tube appeared defective examination with a probe too frequently revealed the fact that the tube was not in correct position for drainage. Estlander's operation had usually a fatal termination and a modified Estlander's operation was useless. A pneumothorax should be tapped early and tapped as often as necessary; the ribs should be removed when repeated tapping failed to *give relief. He summed up the treatment briefly thus:* (1) if air alone was present and the symptoms were not urgent the case should be left alone to recover; and (2) if fluid formed it was necessary to find out whether rum or pus were present. If serum were found the air ould be absorbed and the case would run the course of an dinary serous effusion. If pus were found the prognosis of neglect in such cases was so grave that he recommended [illegible] ld be opened and freely washed out at once.

[illegible] **AN RAW** (Liverpool) briefly described 13 cases [illegible] othorax. Two had been treated by incision and [illegible] tubercle bacilli were found. Both had become septic and died. Of 11 others treated by aspiration two [illegible] *repeated aspiration. He considered that* [illegible] as were urgent cases of tuberculous pneumo- [illegible] be left alone. He did not agree with Dr. West as to the advisability of incision in tuberculous cases, as in his experience the wound was slow in closing [illegible] the question of [illegible] tuberculin as means of diagnosing tuberculous effusions. He considered free exposure to open air as valuable a method of treating tuberculous pleurisy as other tuberculous conditions. During the time a tuberculous pleural effusion existed raw meat was very valuable. He recommended early aspiration, if possible within the first 24 hours of discovering the presence of fluid. The fewer drugs administered the better. Potassium iodide, indeed, was injurious in many cases; diuretics were useless.

Dr. **T. D. ACLAND** (London) did not recommend early tapping for serous pleural effusion in children as he had seen it absorbed rapidly when left alone. He doubted the possibility of pleural adhesions forming as a consequence of *leaving a small amount of tuberculous fluid in the pleural* cavity. If the effusion was purulent the correct line of treatment was more difficult to decide; if the condition was confined to the pleura, forming a local tuberculous abscess, it should be dealt with; if it were part of a general tuberculosis it should be left alone. He had practised washing out the pleura but had found that on opening the chest wall pyogenic organisms entered and made matters worse. In hæmorrhagic effusions frequent tapping was the best method of treatment. As regarded the treatment of pyopneumothorax *he could not agree with Dr. West that the case should* be dealt with according to the ordinary surgical principles in presence of a pus-secreting cavity. Certain urgent cases demanded immediate operation but the majority should be left alone.

Dr. **J. BARR** (Liverpool) demonstrated his method of syphoning fluid from the chest, followed by the pumping in of sterilised air and a small quantity of adrenalin. This latter remedy, he believed, prevented further accumulation of fluid.

Dr. **J. E. SQUIRE** (London) endorsed the views of Dr. West. Pneumothorax rarely required urgent operation; the patient should be watched carefully for the first few hours after the onset of the pneumothorax; if he survived the first half to one hour he usually recovered.

Professor **OSLER**, in reply, urged the great benefit attending early aspiration in pleural effusion.

Dr. **RAW** read a paper on

Human and Bovine Tuberculosis

in which he summarised his communication at the British Medical Association meeting in 1903.[1] *He considered that* man was attacked by two varieties of the tubercle bacillus: (*a*) bovine tubercle, occurring especially in children fed on tuberculous cow's milk, attacking chiefly the serous membranes, bones, and glands, the disease in this case being chronic and less dangerous than (*b*) human tubercle, the usual form met with in adults, attacking especially the lungs, due to inhaled dry sputum or contagion, the disease in this case being more acute and dangerous. In cattle a general tuberculosis had been produced by inoculating them with tubercle *obtained from young children*, but when cattle were inoculated with adult tubercle they had remained healthy. It was probable that these types were antagonistic and that bovine tuberculosis in children protected them from adult human tuberculosis. He was at present engaged in taking the serum from tuberculous cattle with the intention of employing it for the cure of adult human tuberculosis.

Dr. **W. MITCHELL STEVENS** (Cardiff) read a paper on the

Clinical Features of Splenic Anæmia,

and described eight cases that had come under his observation.

---

[1] THE LANCET, August 15th, 1903, p. 473.

Dr. H. LEWIS JONES (London) read a paper on the

Current Curves of Medical Induction Coils.

Oscillograph tracings were shown with the lantern and these demonstrated that the presence of an iron core had the effect of lengthening out the discharge waves. Long windings also had this effect but their influence was less than that of the iron core. Long impulses stimulated sensation painfully; short impulses acted well upon motor fibres and muscle. Short coils without iron acted almost painlessly upon muscle. As the iron core was necessary for the operation of coils, unless an independent mechanical break could be employed, Dr. Jones advised the use of a copper tube as a regulator when testing muscle, the copper tube to be interposed between the core and the secondary windings. Currents interrupted mechanically were likely to replace coil currents for accurate work. Dr. Jones showed a form of interrupter which he had used to the complete exclusion of coil currents for the testing of muscles during the past six months in the electrical department at St. Bartholomew's Hospital. It was superior to the coil because its currents could be measured, it was less disagreeable to the patients, and its curves of current were always alike. Tracings of the current of this instrument were shown.

Mr. HASTINGS GILFORD (Reading) exhibited a collection of photographs of cases of

Ateleiosis and Progeria,

and showed four living instances of ateleiosis. The word ateleiosis (not arriving at perfection) had been applied to a form of delayed development or infantilism, differing from other kinds of infantilism in having no obvious cause and in being of very pronounced type. There were two varieties: 1. The asexual variety in which the development of the sexual organs was more backward than that of any other part. A man, aged 30 years, was shown whose sexual organs were infantile; his facial appearance, height, weight, proportions, dentition, and ossification were childish. Growth was continuing at a very slow rate. His mind seemed to be that of a child who had undergone many years of experience. A second case of the same variety was exhibited, that of a boy, aged 14 years, whose development was like that which is usual at seven years of age. 2. An instance of the sexual variety of ateleiosis, a man, aged 38 years, was shown. His size, proportions, facial characters, and dentition were those of childhood, but in regard to his skeletal and generative organs he was a man. He was married to a woman of ordinary stature and was the father of seven children, of whom all were of ordinary size except one. This exception was a boy, aged 12 years, whose stature and skeletal and general development were equal to those which are usual at about half his age. This boy (who was also shown) seemed to serve as a connecting link between the two varieties of ateleiosis. Charles Stratton or Tom Thumb was a good instance of the sexual form of ateleiosis. The word progeria (*progeros*, prematurely old) was used for a disorder of the opposite nature to ateleiosis, those affected with it becoming senile with great rapidity. Enlarged photographs of two of these cases were shown. One of these patients died from angina pectoris at 18 years of age. The post-mortem examination showed advanced calcareous degeneration of the heart and aorta and other senile changes.

SURGERY.

THURSDAY, JULY 28TH.

Mr. J. BLAND-SUTTON (London) opened a discussion on

Hysterectomy.

He commenced by pointing out that while hysterectomy was only performed by the abdominal route the results were certainly bad but that they began to improve immediately the vaginal route was adopted. Even then, however, the remote results were unsatisfactory. He continued: "The principles on which the operation of hysterectomy should be based depend on the proclivities of the disease. Thus cancer of the cervix of the uterus mainly affects those who have been pregnant and tends to spread to the adjoining surfaces of the vagina and so to the bladder and rectum. Cancer of the body of the uterus, on the other hand, affects mainly elderly unmarried women and tends to spread to the broad ligaments and to the Fallopian tubes. Primary cancer of the Fallopian tubes was first described in 1888. The uterus may also have to be removed for fibroids. In some respects hysterectomy for fibroids surpasses in importance the operation of ovariotomy itself. The fibroids which are especially troublesome from hæmorrhage are the soft myxomata and some of these have been called sarcomata but I do not believe that fibromata ever become sarcomatous. There are four reasons why hysterectomy may be required for fibroids: (*a*) from long-continued hæmorrhage; (*b*) from gangrene of fibroids; (*c*) impaction of fibroids; and (*d*) because the fibroids threaten the patient's life during the puerperium. Enucleation of fibroids is practically impossible except in a few cases. In young married but sterile women it may be worth while to endeavour to remove uterine fibroids while leaving the uterus, but in only a few instances have the patients subsequently become mothers. In nine instances I have removed fibroids from a pregnant uterus and in only one case was the child not born alive. With regard to the exact mode of operation, those who advocate panhysterectomy say that the danger to the ureters is exaggerated but the danger to the ureters is *not* exaggerated, for in 152 cases in which the uterus and cervix had been removed for carcinoma the ureters were damaged in 19 cases. I consider that as a rule the supravaginal operation is the best for sterile women with a long cervix, but if the patient has borne children and is over 40 years of age, then panhysterectomy is to be preferred. One argument that has been used against the supravaginal operation is that the cervical stump is liable to become cancerous. This objection is well founded in a very few cases, but generally when the disease appears in the stump after supravaginal hysterectomy, it is because the disease is already affecting the cervix at the time of operation. Less than 20 years ago it was almost a routine practice to remove the ovaries and to leave the uterus in cases where there was much hæmorrhage from fibroids. I am sure that the reverse is the better course—namely, to remove the uterus and to leave the ovaries. The patient is very much better if she possesses her ovaries and even if only a portion of an ovary can be left it is an advantage. It is true that the benefit of leaving the ovaries is only temporary, for after hysterectomy they always atrophy, but the menopause thus produced is far better than the sudden menopause produced by double oöphorectomy. Another condition requiring hysterectomy is diffuse adenomyoma of the uterus which is very often mistaken for carcinoma. Acute septic endometritis has been treated by hysterectomy, but it can only very rarely be successful. Hysterectomy will also be required when the uterus has been involved in a tubal pregnancy. As to the "ethical" aspect of hysterectomy, some have doubted the justifiability of the operation, but it must not be forgotten that the uterus is merely a temporary organ, active for only 20 or 30 years, and that after it ceases to become capable of fulfilling its functions a woman may be perfectly well. Therefore if disease requires it there need be no hesitation in performing a hysterectomy on this account." Mr. Bland-Sutton did not describe the operation but distributed a pamphlet containing a description of his methods.

The discussion was continued by the reading of a paper by Mr. ALBAN H. G. DORAN (London). He described a case of Fibromyoma of the Mesentery weighing 30 pounds. After referring to the literature of the subject collected by Bégouin and Julliard Mr. Doran related the particulars of his own case. The patient was a woman, aged 34 years; she had noticed an abdominal swelling for about six months; it grew very large without causing any pain or symptoms of obstruction. It was soft and gave a sense of fluctuation. A diagnosis of ovarian tumour was made. On exposure at the operation it was found to be invested by the anterior or upper layer of the mesentery. It was enucleated with ease as there were no adhesions; nor was any resection of intestine necessary. The capsule was drained and the patient made a good recovery. Mr. Doran described the anatomy of the capsule in this and in similar cases and spoke of tumours encapsuled in other peritoneal folds besides the mesentery proper. A table was given containing clinical particulars of the case and of 12 other cases of the fibroma and myoma type encapsuled in the mesentery. In three of these cases the patient was a male; hence tumours of this class did not necessarily arise from elements associated with the female genital tracts. The question of diagnosis was discussed. As to treatment, if the growth was a fibromyoma removal by operation though dangerous was the right course. The precise relations of the tumours varied greatly and extensive resection of bowel was often needed, especially when there was a *relatively small tumour involving several* coils of intestine in its capsule All the 13 operations in the table were complete except one which ended fatally Possibly complications might be met with in future cases, as in operations for other types of mesenteric tumour Lastly, the treatment of shock after the removal of such large tumours and the management of the capsule were considered

In continuation of the discussion Mr C H J LOCKYER (London) read a paper on the Special Features and Modes of Treatment of True Cervical Fibroids, giving an account of two cases In the first of these the tumour was removed by myomectomy, it was a very large growth in a woman, 22 years of age The upper limit reached *to the umbilicus* but *owing to the fact that the* tumour had caused full dilatation of the os uteri its removal was not difficult The uterus involuted well and measured only two inches by the sound one month after the operation Two and a half years later the patient returned with a similar growth in the cervix and panhysterectomy was performed and the recovery from operation was complete Both tumours were true cervical fibroids and both were benign In the second case a true cervical fibroid was diagnosed by the corpus uteri being felt lying upon the tumour and not entering into its formation, and by the tumour fitting into the vagina like an egg in an eggcup, by the absence of vaginal cervix, and by the high anterior displacement of the external os The tumour and uterus were removed by abdominal panhysterectomy, and the patient recovered The uterus was very adherent to the bowel and it contained 12 other growths besides the large cervical fibroid Mr Lockyer drew a sharp distinction between the interstitial cervical fibroids which are invested by the wall of the cervix and so called cervical fibroids which grow out from the cervix into the parametrium *For true* cervical fibroids myomectomy was the operation *par excellence*, but the cases referred to were exceptions to this rule In the first case after myomectomy had been performed recurrence took place the simple nature of which was not discovered until after the second operation In the second case there had been clinical evidence of adhesions of the bowel to the body of the uterus and it was deemed wise therefore to operate by the abdomen

In the subsequent discussion the following took part Dr J A SHAW MACKENZIE (London), Mr E STANMORE BISHOP (Manchester), Professor MURDOCH CAMERON (Glasgow), Mr F BOWREMAN JESSETT (London), Mr C MARTIN (Birmingham) Mrs SCHARLIEB, M D (London), and Mrs BOYD, M D (London)

Mr R A BICKERSTETH (Liverpool) read a paper on Catheterisation of the Ureters

Mr A H TUBBY (London) read a paper on the

Operative Treatment of Muscle Grafting for Paralysis of the Serratus Magnus Muscle

He said that the deformity was sometimes bilateral but more often unilateral It arose from a variety of causes unnecessary to enumerate In the case quoted it was probably due to infantile paralysis The patient was a girl, seven years old, the left scapula stood out from the body On abducting the arm to the horizontal position *the scapula was nearer to the vertebral column than on the* sound side and the posterior border stood out so much from the chest that the fingers could be inserted beneath it so as to grasp at least the lower third of the bone When the left arm was put forward horizontally in front of the chest the posterior edge of the scapula receded from the thorax, causing a deep groove at this part Elevation of the arm above the shoulder was much weakened and there was considerable diminution in the reach of the left arm The external thoracic nerve and the muscle itself gave the reaction of degeneration It appeared to be hopeless to expect any improvement by the usual methods of massage and electricity, so Mr Tubby determined to try to transfer some power from a healthy muscle He decided to attempt to utilise a portion of the pectoralis major An incision was made over the anterior border of the axilla, a flap of skin and subcutaneous tissue was then turned down and a large part of the sternal portion of the pectoralis major was exposed, its attachment to the humerus was then freed and the muscular fibres of this portion were separated from the surrounding tissues for a considerable distance Then the serratus magnus was exposed and was found to be pale and atrophied The cut end of the pectoralis major was separated into several fasciculi and these were then stitched into the serratus magnus over an area corresponding to four or five digitations of the latter The wound healed well and six weeks later there was no perceptible difference in the prominence of the inferior angles of the two scapulæ Further, the child could abduct the extended arm well above the horizontal position and had acquired the power of thrusting the arm forward The improvement had been fully maintained up to the present time and there was no loss of power in bringing the arm across the chest, in spite of the diversion of part of the pectoralis major Although this was a single case the method deserved further trial

Dr HERBERT SNOW (London) read a paper on

Cancer Facts and Fallacies,

in which he advocated the formation by the British Medical Association of a cancer committee the duty of which should be to put on a scientific basis the numerous facts already known respecting the causes and phenomena of cancer It was essential that the cases of cancer should be properly classified, as at present the facts concerning various forms were all put together rendering valueless any conclusions that might be deduced from them

OBSTETRICS AND GYNÆCOLOGY

WEDNESDAY, JULY 27TH

The proceedings were opened by the President Dr F H CHAMPNEYS (London) cordially welcoming Professor Olshausen and Professor Schultze of Berlin to the meeting He then called upon Sir ARTHUR V MACAN (Dublin) to open a discussion upon the

Treatment of Accidental Hæmorrhage

In the course of a valuable and well thought out paper Sir *Arthur Macan reviewed the nature, causes and mechanisms* involved in the consideration of cases of accidental hæmorrhage He said that no satisfactory treatment had so far been devised for dealing with accidental hæmorrhage—that at any rate was the dictum of Holmes to whom he expressed his indebtedness for a paper previously published on the subject He considered that systematic plugging of the vagina was the best procedure He carefully reviewed the conditions of disease which gave rise to accidental hæmorrhage—e g scurvy hæmophilia nephritis and the like, and showed how these conditions lent themselves to defeat the forces of nature usually employed in order to arrest hæmorrhage He also discussed the mechanisms of labour which led to premature separation of the placenta as regards the uterus—e g, the contraction ring of Bandl the internal os the conditions of the uterine walls and the like, the condition as regards the placenta—unusual sites of insertion, short cord, and variations of intra uterine pressure, and stated that he did not believe that a healthy uterus could be over-*distended by blood clot He dealt with the subject under* five chief heads (1) causes of the hæmorrhage, (2) causes increasing the hæmorrhage (3) causes lessening the hæmor

ppear externally, and (5)

and he then discussed two

ure of the membranes and

(2) the result of uterine contraction The consideration of *the first led him to decide in* favour of plugging the vagina in preference to rupturing the membranes He considered that the tone of the uterus controlled the hæmorrhage and if the hæmorrhage was small and primary then it was in the centre of the placental site and gradually extended in concentric rings outwards and that the uterine contractions tended to diffuse the hæmorrhage and to cause it to spread Rupture of the membranes

and so increased the hæmo

commence to contract then

hæmorrhage In certain cases the contractions of the uterus actually increased the hæmorrhage Every hæmorrhage was originally internal and there were many degrees between the internal and the external The signs of hæmorrhage were pain, tension, and anæmia and external blood and clots The symptoms were out of all proportion to the amount of blood lost The diagnosis of combined internal and external hæmorrhage was most difficult With regard to treatment he considered prophylaxis was important as in hæmophilia, scurvy, nephritis, and the like The hæmorrhage should, if possible, be stopped without emptying the uterus, if this were not feasible then the uterus

Dr. H. LEWIS JONES (London) read a paper on the

Current Curves of Medical Induction Coils.

Oscillograph tracings were shown with the lantern and these demonstrated that the presence of an iron core had the effect of lengthening out the discharge waves. Long windings also had this effect but their influence was less than that of the iron core. Long impulses stimulated sensation painfully; short impulses acted well upon motor fibres and muscle. Short coils without iron acted almost painlessly upon muscle. As the iron core was necessary for the operation of coils, unless an independent mechanical break could be employed, Dr. Jones advised the use of a copper tube as a regulator when testing muscle, the copper tube to be interposed between the core and the secondary windings. Currents interrupted mechanically were likely to replace coil currents for accurate work. Dr. Jones showed a form of interrupter which he had used to the complete exclusion of coil currents for the testing of muscles during the past six months in the electrical department at St. Bartholomew's Hospital. It was superior to the coil because its currents could be measured, it was less disagreeable to the patients, and its curves of current were always alike. Tracings of the current of this instrument were shown.

Mr. HASTINGS GILFORD (Reading) exhibited a collection of photographs of cases of

Ateleiosis and Progeria,

and showed four living instances of ateleiosis. The word ateleiosis (not arriving at perfection) had been applied to a form of delayed development or infantilism, differing from other kinds of infantilism in having no obvious cause and in being of very pronounced type. There were two varieties: 1. The asexual variety in which the development of the sexual organs was more backward than that of any other part. A man, aged 30 years, was shown whose sexual organs were infantile; his facial appearance, height, weight, proportions, dentition, and ossification were childish. Growth was continuing at a very slow rate. His mind seemed to be that of a child who had undergone many years of experience. A second case of the same variety was exhibited, that of a boy, aged 14 years, whose development was like that which is usual at seven years of age. 2. An instance of the sexual variety of ateleiosis, a man, aged 38 years, was shown. His size, proportions, facial characters, and dentition were those of childhood, but in regard to his skeletal and generative organs he was a man. He was married to a woman of ordinary stature and was the father of seven children, of whom all were of ordinar
size except one. This exception was a boy, aged 12 year
whose stature and skeletal and general development we
equal to those which are usual at about half his a
This boy (who was also shown) seemed to serve as a conn
ing link between the two varieties of ateleiosis. Ch
Stratton or Tom Thumb was a good instance o
sexual form of ateleiosis. The word progeria (pr
prematurely old) was used for a disorder of the c
nature to ateleiosis, those affected with it becomir
with great rapidity. Enlarged photographs of twc
cases were shown. One of these patients died fr
pectoris at 18 years of age. The post-mortem e
showed advanced calcareous degeneration of th
aorta and other senile changes.

SURGERY.

THURSDAY, JULY 28TH.

Mr. J. BLAND-SUTTON (London) opened a discussion on

Hysterectomy.

He commenced by pointing out that while hysterectomy
was only performed by the abdominal route the results wer
certainly bad but that they began to improve immediatel
the vaginal route was adopted. Even then, however, th
remote results were unsatisfactory. He continued: "Th
principles on which the operation of hysterectomy should be based depend on the proclivities of the disease. Thus cancer of the cervix of the uterus mainly affects those who have been pregnant and tends to spread to the adjoining surfaces of the vagina and so to the bladder and rectum. Cancer of the body of the uterus, on the other hand, affects mainly elderly unmarried women and tends to spread to the broad ligaments and to the Fallopian tubes. Primary cancer of the Fallopian tubes was first described in 1888. The uterus may also have to be removed for fibroids. In some respects hystere

[illegible] abdominal route afforded easier access to the diseased areas and permitted of a more orthodox anti cancerous operation than the vaginal route though, of course, there were many cases in which the vaginal operation advocated by Professor Olshausen was the most correct method, both from the surgeon s and patient s point of view

Dr F EDGE (Birmingham) said that it must often be a question as to whether, after the vaginal operation for the removal of the uterus all had been done that could be done for the patient but having heard the able advocacy of so distinguished an authority as Professor Olshausen he thought that the vaginal route for removal of preferable and only in certain other toneal adhesions, atresia, and so on operation be indicated

Dr MARY SCHARLIEB (London) entered a strong plea for a more favourable view of the abdominal route for the removal of the cancerous uterus especially in these days of improved technique in abdominal surgery There were cases —e g , nullipar e—where owing to a contracted and narrow vagina the vaginal operation was not easy or even possible then there were cases where adhesions from old peritonitis would be a source of danger

The PRESIDENT made some commendatory remarks on the paper and Professor OLSHAUSEN replied briefly to the remarks of the foregoing speakers, saying that there were of course certain circumstances in which the abdominal route would be desirable nevertheless the vaginal route was in his opinion and experience, the one most to be preferred

Dr ROBERT KENNEDY (Glasgow) read a paper entitled

The Treatment of Birth Paralysis of the Upper Extremity by Suture of the Fifth and Sixth Cervical Nerves

He dealt with the nature and causation of the lesion which he attributed to either partial rupture or complete rupture with cicatricial obstruction of the nerve He discussed at length the distribution of the paralysis as affecting the deltoid the spinati and so on He carefully considered the indications and time suitable for the operation and pointed out the necessity for moderately early operation as tending to more rapid recovery especially due to the fact that the muscles were more easily restored than if the operation were long delayed , on the other hand he pointed out that even in cases of long standing a great deal might be done He gave an interesting and instructive account of cases which he had operated upon and showed photographs of children whose full powers had been restored after operation He also carefully described the procedure of the operation necessary for excision of the injured portion of the nerves and their reunion He strongly deprecated the joining of the cut ends of the nerves to other than their

ns were done the result was

Dr Kennedy on his success and invited discussion

Dr HELME said that he had not seen any cases of Duchenne s paralysis and thought that certain unknown factors tended to its non observance He al o complimented Dr Kennedy on his results

Dr MUNRO KERR and Dr CAMPBELL congratulated Dr Kennedy on his results The latter said that he had during the last few years seen 20 cases at the children s hospital where he was surgeon and that he had successfully operated on many of them after the manner recommended by Dr Kennedy

THURSDAY, JULY 28TH

The proceedings were opened by the PRESIDENT calling upon Dr J SINGLETON DARLING (Lurgan) to read his paper entitled

Removal of Fibromyoma of the Left Ovary 22¼ Pounds in Weight

an account of a rapidly growing fibroid tumour containing some muscular tissue which had contracted adhesions in the peritoneal cavity, thereby rendering its removal somewhat tedious The presence of a well marked sulcus on its surface

some of his colleagues to be in

free and there was no ascites

mour of its kind on record in

Dr C L PURSLOW (Birmingham) said that it appeared to

rium fibroid as one of

[illegible] ligament fibroids

Dr J S FAIRBAIRN (London) pointed out that the specimen shown did not appear to be strictly ovarian as the ovary was not spread out o [illegible] usually the cas

) agree with

Dr

Dr EWEN J MACLEAN (Cardiff) agreed with Dr Purslow and Dr Fairbairn and said that the freedom of the uterus from adhesions to the tumour and elsewhere and, also the absence of ascites were noteworthy and interesting

The section on the motion put by the PRESIDENT, appointed Dr Purslow Dr Fairbairn, and Dr Maclean as a committee to consult with Dr Darling as to the exact nature

our and report to the meeting subsequently The

to the effect that there were not sufficiently exact

data available to enable them come to a definite conclusion

Dr F J MCCANN (London) next contributed a paper on

Two Cases of Urethro vaginal Fistula treated by Operation

The first case was highly interesting and instructive and was that of a primipara who had had a lingering first stage of labour with somewhat late application of forceps to a non descending head Subsequently she suffered from retention of urine The further history of the case was that ten days afterwards serious trouble with her bladder supervened and one month after her confinement she was put under the care of Dr McCann at the Samaritan Hospital, when it was found that the posterior wall of her bladder and urethra were in a sloughing condition and their subsequent separation laid the bladder urethra and vagina into one continuous cavity The patient was with great difficulty brought through the primary stages of her illness and gradually improved till the time when operation could be entertained for the remedy of the existing conditions Dr McCann described the difficult and ingenious operation undertaken for restoration of her bladder functions which was successful to a great extent, but he said that the bladder cavity now remaining was a contracted fibrous sac incapable of holding much urine which necessitated the constant use of a urinal He had found it difficult to obtain dilatation of this sac so far The second case was one where the base of the bladder and urethra was crushed by the delayed fœtal head He described the operation undertaken which was highly successful in every respect He further described an ingenious operation deduced from the foregoing cases and intended to remedy incontinence of urine supervening on over dilatation of the urethra from any cause

The PRESIDENT expressed great satisfaction at having heard Dr McCann s most interesting paper and suggested that in endeavours to dilate the contracted bladder the distensive pressure used should be very slight for he had noticed that in many cases some incontinence present was due to irritability and not so much to lack of space therefore gentle graduated pressure in these cases was more efficacious than the more forcible and abrupt applications It was also most interesting to note the success and efficacy of Dr McCann s attempts to repair the urethra

The three following papers presented material of uncommon pathological and practical scientific interest and were discussed together with evident appreciation by the entire section

Dr E SMALLWOOD SAVAGE S (Birmingham) paper was entitled

An Early Case of Chorion epithelioma following Hydatid Mole

This was a carefully worked out account, clinical and pathological of a case in which subsequently to the removal of a hydatid mole signs of malignant disease appeared The

The uterus was removed

nodule in the posterior wall

in the left cornu uteri An excellent series of enlarged photo micrographs illustrating the minute pathological histology were shown, as well as a complete series of lantern slides

The paper by Mr CHRISTOPHER MARTIN (Birmingham) on

A Case of Deciduoma Malignum

was of a s[illegible] cellent collection of m[illegible] logy of the condition [illegible] d and lucidly explained

The paper by Dr. T. WILSON (Birmingham) on

A Case of Chorion-epithelioma

was a clear account of a rapidly growing neoplasm of the uterus in a young woman extensively involving surrounding tissues and organs. The series of lantern slides exhibited were of especial interest. At the end of his paper he stated that Professor R. F. C. Leith of the University of Birmingham had written a pathological commentary on the three foregoing cases and asked the permission of the meeting to read the same. The commentary dealt with the possible mode of origin and growth of the disease and was an enlightening and instructive exposition of the behaviour and mode of invasion by the epithelium of the chorionic villi.

Dr. MACLEAN said that there was really a very small margin between simple hydatid mole and malignant hydatid mole from a microscopical standpoint. The microscopical distinctions should be clearly understood and carefully applied in order to prevent the removal of a uterus for a non-malignant mole and the retention of a uterus which was the seat of disease after malignant mole.

Dr. McCANN said that he agreed with Dr. Maclean that chorion tumours of the uterus were not all malignant. In many cases where syncytial masses were absent a high degree of malignancy was developed.

Professor BYERS next read a paper entitled

Suggestions for the Prevention of Puerperal Infection in Private Practice.

Attention was drawn to the progress in the general results of midwifery practice since the introduction of the antiseptic and aseptic methods. This was specially noted in the case of maternity hospitals. Professor Byers gave the statistics from two maternity hospitals—the Rotunda in Dublin and the Belfast Lying-in Hospital—showing that for the past two years out of a total of 8796 cases the total mortality was 0·31 per cent. and the mortality from sepsis was only 0·09 per cent. Turning to general practice he showed by the statistics given him by the Registrars-General of England, Scotland, and Ireland that the same good results were not procured. During the past 20 years 40 per cent. of the total childbed mortality was due to septic diseases. In England and Wales in 1901 2079 deaths in childbed were due to puerperal fever and 2315 were from other causes, accidents and so on. He thought that the difference in these results in maternity hospitals and in private practice must be explained as being due (1) to inefficient practical teaching and clinical training of students and midwives; (2) to the fact that the details of the antiseptic and aseptic methods as employed in maternities were not so carefully observed in private practice; and (3) to a tendency in some cases to meddlesome interference. Certain facts were then brought forward as to the nature of puerperal infection and suggestions were offered for its prevention. The dangers of vaginal examinations in labour were emphasised and the value of abdominal palpation was insisted on and it was urged that nature's action in labour should not be thwarted unnecessarily or supplanted by the methods of art. Nature should be followed and aided, and only when, for one reason or another, the resources of nature proved inefficient should the obstetrician interfere and then he should take the same precautions as the surgeon now did when he performed an operation.

After some remarks from the PRESIDENT, Dr. R. MOWBRAY (Castlederg), and Mr. W. G. NOBLE (London),

Dr. E. T. DAVIES (Liverpool) said that puerperal fever was invariably found in the practice of midwives and not in that of medical men, and trusted that in future owing to the better training of midwives matters would be improved. He cordially condemned the practice of repeated vaginal examination during labour.

Dr. H. CORBY (Cork) thought that undoubtedly repeated vaginal examination caused sepsis and that very often syringing was also the cause of infection. Phlegmasia dolens was, in his opinion, due to septic infection and it would usually be found that the sanitary arrangements of the domicile were out of order.

Dr. J. WARD COUSINS (Portsmouth) said that all obstetric cases should be treated as if they were surgical cases. He also thought that abdominal palpation was now much more used than formerly.

The PRESIDENT thought that those who had syringed their patients formerly should not be blamed, as they were really the pioneers and founders of modern practice and did the best they could in the past. It was therefore not correct to criticise them by the very standards which they had worked so hard to set up.

Dr. MUNRO KERR read a paper on

Cancer of the Cervix complicating Pregnancy, with Cases.

He carefully reviewed the existing practice in these cases and discussed the advantages and disadvantages of (1) panhysterectomy; (2) Cæsarean section followed by panhysterectomy; (3) Cæsarean section followed by vaginal hysterectomy; (4) Cæsarean section followed by vaginal amputation of the cervix; and (5) vaginal Cæsarean section. He quoted cases illustrating the successful performance of vaginal Cæsarean section.

Dr. WILSON discussed the paper and quoted a case where he performed vaginal Cæsarean section, then split and delivered the uterus per vaginam, removing it and clamping and tying the broad ligaments on either side.

The PRESIDENT regretted that lack of time prevented the full discussion of the preceding paper which was important and interesting.

Dr. MUNRO KERR replied, saying that Dr. Wilson's case was probably the most advanced case illustrating treatment on record.

STATE MEDICINE.

WEDNESDAY, JULY 27TH.

This section met under the presidency of Dr. J. S. HALDANE, F.R.S.

Mr. INNES GRIFFIN took the chair whilst the PRESIDENT read a paper on

Standards of Ventilation.

He said that it was a well-known fact that there was a high death-rate where there was overcrowding or, in other words, a deficiency of air for the number of persons. Much of this could be overcome by ventilation but there were other impurities which rendered the air unwholesome. The effects of vitiated air on health were well known and these he would not refer to, confining his remarks especially to dust, one of the most deleterious constituents. The great mortality among workers in dust-laden air from lung disease had been referred to by many writers and he would endeavour to show how this mortality might be reduced. The death-rate among miners from lung disease was much higher than in any other occupation, while, on the other hand, deaths from other causes were lower. This mortality began at the twenty-fifth year and was maintained at higher ages. The chief cause of the production of dust was the boring machine, an apparatus worked by compressed air, in which frequent and violent blows were given by the drill. When working in certain positions, horizontal or overhead, the drilling had to be done dry and large quantities of dust were created, but if the work was done downwards the hole could be filled with water and very little, if any, dust was created. The rock-drillers suffered most and though few in number in proportion to the number of workmen in a mine the mortality was very high, 74 per cent. dying from tubercle. Coal dust appeared to be less deleterious than rock dust, but in both the dust was cumulative and the damage done was irreparable. Lantern slides were shown of men at work with rock drills. Both in Cornwall and the Transvaal water was used for rock-drilling with most satisfactory results. Poisonous dust such as lead he would not refer to, nor to pollen dust, to which some unfortunate persons were susceptible and on which recent work had been done. There was little doubt that much harm was done by infective micro-organisms, but to what extent they were present in a crowded building it was doubtful, though probably in large quantities. Though ventilation could do much there were other means, more particularly preventive ones. In factories ventilation would not prevent the accumulation of dust and means must be found to avoid as far as possible its formation and dissemination. As regards infective material in rooms expectoration must be avoided as a constant source of risk. In the ventilation of rooms it had been generally assumed that an excess of carbon dioxide was a serious matter. The President did not believe that the amount unless very excessive made any difference at all. He had taken the air in a large number of schools and found it far above that usually stated in books to be positively dangerous, while the children did not suffer. As a matter of fact he had shown that an excess of carbon dioxide in the respired air had a stimulating effect on the respiratory centre and consequently was readily neutralised by increased respiratory effort, the amount of carbon dioxide in the alveolar air remaining constant The amount of aqueous vapour in air above or below normal made little difference Vitiated air had a nasty smell To what was this due? It was supposed to be an albuminous substance, a volatile poison, but in his experiments he could find nothing to warrant this theory The reducing power foul air had on potassium permanganate was due to dust He did not believe this foul air predisposed to phthisis, instancing schoolmasters and teachers, among whom the death rate for that disease was not high The effects of burning gas in a room were not very serious unless a large proportion of sulphur was present All the carbon disulphide should be removed from the gas before supplying it and he regretted to say that there appeared to be considerable laxity among some gas companies in this respect The actual number of germs present in the air was of little importance, as most were non pathogenic It was an established fact that speakers gave off micro organisms and breathers did not, and he believed that the high mortality among publicans from phthisis was due to the crowded, dusty air and loud talking persons who frequented public houses The two important factors in ventilation were warmth and movement and he believed the success of the open air treatment of phthisis was due more to the constant movement of air than to its purity The amount of carbon dioxide in air was still the best standard of the purity of air His own views did not quite agree with those of the Society of Medical Officers of Health which in his opinion had fixed its standard too low for ordinary working purposes

In the discussion which followed attention was called to the fact that the high death rate among older miners was due to the fact that they worked above ground where there were no precautions to prevent dust or to avoid dust explosions Factory owners had found the work better done under more hygienic conditions

Dr **THOMAS OLIVER** (Newcastle on Tyne) believed there was more phthisis in schoolmasters at the present time than formerly From his experience in a coal district he had observed that more dust was made by a hard coal and consequently more phthisis was developed He referred to the wonderful effects of wet drilling as compared with dry, hardly any dust being raised by the former, while in dry drilling it was sometimes impossible to see a person a few feet off

Dr A **HAY** suggested that the increased respirations produced by excessive carbon dioxide would lead to the inhalation of more dust and hence would be deleterious in this way

Dr C J **JONES** believed that the smell of a crowded room was due to clothes and dust, for it had no relation to the amount of carbon dioxide He had found that the smell began when the carbon dioxide amounted to 10 in 10,000 Schoolmasters he looked on as a selected class—selected for sound lungs, besides they were constantly under medical supervision

Dr W H **SYMONS** and Dr J H **HUNTER** also spoke and the **PRESIDENT** briefly replied

At the conclusion of this discussion a motion was passed to be sent to the council
papers should be printe
who wished to take part [illegible]
idea of what the reader of the paper was going to say

Dr **OLIVER** opened a discussion on

Caisson Disease

After describing a caisson and the methods of entering and leaving he said that the first fatal case of the disease occurred while the bridge at Saltash was being built by Brunel The man had been working at a depth of 87 5 feet at a pressure of + 40 pounds The first pathological account of the effects of compressed air was written by M Pol and M, Watelle, two French surgeons, in 1854 Since that time many others had appeared The chief points to be remembered were that with each increase of depth and pressure the men inside should work at a stretch a correspondingly shorter time and the air supplied should be pure and abundant In Newcastle at the present time a large number of men were being employed in caissons In the chamber 34 men could work 750 cubic feet of air per minute was pumped in or 1320 cubic feet per man per hour Up to 25 pounds per square inch the men worked ten and a half hours out of 12 From 25 to 30 pounds they worked from seven and a half to eight hours, and from 30 to 35 pounds about seven hours, above this the time was regulated by the ability of the men to stand the work The time allowed the men to pass through the locks was one minute for each five pounds' pressure Paul Bert was the first to experiment with compressed air on animals and he found an excess of nitrogen Hill and Macleod showed that there was an increase in the absorption of nitrogen but no alteration in the mean blood pressure or pulse rate while the animal was in the chamber When decompression was allowed bubbles of gas were seen in the blood Paul Bert drew attention to the dangers of oxygen at high tension, which acted as a protoplasmic poison causing convulsions and death Lorrain Smith had shown that it might also produce inflammation of the lungs and in this appears to act similarly to ether as a duct irritant The symptoms of the disease came on after the men left the caisson, but might be largely avoided if the men were kept in the lock one minute for each five pounds of pressure The men complained of pains in the limbs (called "bends), often of a very serious character Giddiness, epistaxis retention of urine, unconsciousness and delirium were seen Vomiting, with abdominal pain and analgesia of irregular distribution on the legs, sometimes occurred Physiologists said that the symptoms were due to the free gas liberated in the blood on the reduction of pressure, the gas being reabsorbed if the pressure was again raised To prevent the disease only healthy men should be selected for work short and thin men being more suitable than tall and stout ones Men about 25 years of age stood the work better than older one, and lengthened service conferred no immunity Shifts and the decompression should last in time in proportion to the pressure

Professor J **LORRAIN SMITH** (Belfast) referred to his laboratory experiments which showed the effervescence of the nitrogen on reduction of pressure, but he was not quite satisfied that this alone would account for all the symptoms How was it that age made a difference in liability? Was it due to a better collateral circulation? Could not the oxygen be accountable for some of the symptoms, for experiments tended to show that it had a serious effect on certain animals?

Dr E H **SNELL** (Coventry) detailed his experience at the Blackwall tunnel, in which the caisson was placed horizontally and not vertically, thus introducing many difficulties and requiring, when passing through gravelly soil, a very large quantity of air

Dr **OLIVER** replied

Dr G F **McCLEARY** (London) read a paper on the

Influence of Antenatal Conditions on Infant Mortality,

but owing to the lateness of the hour there was no discussion

Dr D E **ANDERSON** (Paris) handed in a remark to the chairman stating that he believed that excessive drinking of fluids during pregnancy led to venous congestion, excessive liquor amnii and consequent stretching of the umbilical cord

In the subsection of Forensic Medicine, presided over by Sir **THOMAS STEVENSON**, papers were read by Dr F **SMITH** on the Civil Responsibility of the Insane, by Dr H H **LITTLEJOHN** (Edinburgh) on Wounds of the Throat, with lantern demonstration, by *Dr F G* **WALDO** *(London)* on Notes on the Klosowski Antimony Case, by Mr R L **WILLCOX** (Warminster) on Infantile Mortality from Over lying, and by Dr **PARKINSON** on Rigor Mortis in Newly Born Infants from a Medico legal Point of View

THURSDAY, JULY 28TH

Dr G **NEWMAN** (London) opened the discussion on

Milk supply

He said the reason why a proper and efficient control of the milk supply was necessary was to prevent the conveyance of certain diseases, in which were included enteric fever, scarlet fever diphtheria, sore throats followed by illness and aberrant forms of disease, epidemic diarrhœa and tuberculosis After referring to these in brief detail Dr Newman said that the belief in this country was that tuberculosis could be conveyed by milk to human beings from cows, but that it probably followed when the udder was affected with that disease About 20 per cent of cows suffered from tuberculosis but in only 2 per cent was the udder diseased Taking the number of cows in this country as 80,000, yielding an average of 400 gallons per annum, as much as 32,000,000 gallons of milk were supplied open to grave suspicion and requiring careful watching. Over half the population of this country live [illegible] to them that the chief difficulties of [illegible] The problem was the time that was [illegible] milking of the cows and the supply to the consumer. There was practically no control. The sheds were dirty, the cows were dirty, the milkers were dirty, the methods of transport were inadequate, and on being delivered at the retail dealers no means were taken to keep the milk clean. Besides this the consumer often received the milk in dirty jugs and made no effort to keep the milk from dust or dirt. Railways made no special provisions for conveying milk, as was done in Denmark; indeed, the carrying of milk hardly paid the cost. The consumption of milk—such a necessary food for many—was far below in amount what it should be, the average working out at 39 gallons per person per annum, though among the poor this was really much lower, even as little as 1·7 ounces a day. The import trade in milk was increasing and unless the dairy farmers woke up would increase still more. The question of control was treated on broad principles and in Dr. Newman's opinion the demand for reform must come from the consumer. As soon as he let the supplier know that a pure milk of good quality was insisted on the dairy farmer would set to work to supply it. There must be coöperation between the milk vendor and the dairyman, and legislation, instead of hindering both vendor and dairyman, must tend to encourage the trade in milk. At the same time the present legislation must be enforced. The details for reform proposed were that the cows—a good breed being selected—should be kept clean, the animals should be regularly inspected by a veterinary surgeon, the water-supply should be good, and the cowsheds should be kept clean—in short, there should be perfect sanitation of the cowhouses. Sterilisation will not make a dirty milk clean. In addition to this there should be a systematic training in dairy work. Then, too, better railway conveyance was important and Dr. Newman showed how much neglected from a sanitary point of view the conveyance of milk was. At the present time milk-shops had to be licensed, but there was no power to refuse or take away a licence on the score of insanitary premises or neglect of proper precautions. To some extent the supply of dirty milk might be got over by selling it in bottles. Home contamination must be avoided by instruction and much might be done in this direction by visitors among the poor and school teaching. The question how much the selling of modified milk reduced the mortality from milk-borne diseases was next touched on and reference was made to various municipal milk-supplies and the institutions working on much the same lines on the continent.

In the discussion which followed Dr. HENRI DE ROTHSCHILD (Paris) emphasised the importance of the consumer demanding a pure supply; this had been done in France with the best results. Among the poor the question was one of price. He described the methods employed in Paris and said that their results had greatly improved since they began this work in 1897.

Dr. C. R. DRYSDALE (London) said he believed that many of the large firms selling milk in London conducted their business on the best and most sanitary principles. He believed the conveyance of tubercle by milk was very rare; enteric fever, everyone knew, was carried by it, but this arose from the use of infected water for washing the cans.

Dr. S. HALLOWS (London) said he had visited over 50 farms about London and in none had he found the condition satisfactory. The cowhouses were dirty, hung with cobwebs, contaminated by adjacent cesspools, while the milk-cans were dirty beyond conception. He considered inspection by proper officers most essential. The railway companies must be made to carry milk in proper vans and the cans must be sealed. He said it was not an uncommon thing for the porters to open the cans and help themselves to the milk by dipping dirty cups into the milk. The flower-sellers of the West had insisted on special trains and the milk-sellers should do the same. He considered instruction of the people of prime importance and condemned all condensed milks as insufficient in nourishing qualities.

Mr. T. LAFFAN (Cashel) said that many persons could not obtain milk in the winter but means should be taken to enable them to. He insisted on a fixed standard for milk.

Dr. G. F. MCCLEARY (London) thought that the reform should not have to come through the consumer but the supplier. The cow was the dirtiest animal on the face of the earth. What was required was cleanliness in production but this unfortunately led to increased cost.

Mr. STOKES, a local farmer, suggested that a conference should be held by the farmers, veterinary surgeons, and medical men. Farmers were quite ready to follow any reasonable suggestions and he believed that bottling the milk would prove a remedy for most of the evils.

Dr. NEWMAN briefly replied.

Dr. C. J. THOMAS (London) read a paper entitled

Experience of School Diphtheria in the Metropolis.

He had attempted to estimate the proportion of the total amount of diphtheria attributed to school influence, this being most amenable to control. [illegible] brought about by the whole [illegible] brought under one hygienic [illegible] diphtheria was a personal d[illegible] of investigation [illegible] on the importance of class inspection [illegible] attendance registers. The children who spread the disease might be divided into four classes: (1) slight unrecognised cases presenting no symptoms; (2) recrudescence of infection in cases after absence for notified diphtheria; (3) cases coming from infectious houses; and (4) those who carried the disease without having symptoms or demonstrable contact. The prevalence [illegible] population was discussed and [illegible] bacilli. Protracted infection was considered and its bearing on the practice of school closure. Closure was unscientific and unnecessary where proper facilities for bacteriological investigation existed. There was needed also education on the subject not only among the general public but also among the general practitioners and the medical officers of health were the persons to do this. Disinfection of houses without swabbing of "contacts" was pointed out.

Dr. E. DAVIS, Dr. R. JONES, and Dr. H. JONES joined in the discussion.

Dr. T. W. N. BARLOW (Bootle) read a paper on

The Teaching of Hygiene in Elementary Schools and the Desirability of excluding Young Infants from such Schools.

He referred to some causes of, and efforts made to counteract the causes of, infant mortality and the attitude taken by the education authorities with respect to the teaching of hygiene. He commented on the objections raised and related the scope of teaching adopted at Bootle. He believed it was undesirable to aggregate children at a susceptible age, for it was among those under five years that the greatest mortality occurred.

Dr. K. F. LUTOSLAWSKI (Warsaw) remarked on the absence of any information in text-books on personal hygiene.

Dr. J. MACGREGOR ROBERTSON (Glasgow) believed that successful instruction in hygiene was not practicable. Already the curriculum was too large and to add hygiene to it was to court failure. Instruction in physiology must go with hygiene and an hour a week, the most that would be given to the subject, was too short a time. To this must be added the great difficulties that there would be to demonstrate the value of hygiene.

Dr. JESSIE MACGREGOR (Edinburgh) agreed with the last speaker as regards physiology. Hygiene had been taught most successfully in Japan where instruction was given in physiology, while the teachers received more advanced instruction as well as being taught the care of sick children.

Dr. THOMAS said that expert medical advice was required at the Education Office and Dr. BARLOW thought the teaching of personal hygiene most important.

Dr. ELLIOTT SMITH read a paper on

The Spread of Ankylostomiasis.

It was proved now that infection took place through the skin, the larva working its way down the hair follicles and reaching the blood-vessels and lymphatics. By this means it reached the right side of the heart and pulmonary circulation. From the capillaries it passed into air vesicles and commencing here to grow crept up the bronchi to the trachea, larynx, and epiglottis, to the œsophagus and finally to the duodenum. Here it attached itself. It appeared to live on the epithelium and not to suck the blood, so that the anæmia it produced was probably caused by the formation of some toxic substance, this being possibly formed in two glands situated on the side of the mouth of the larva. The mud of the Nile swarmed with these larvæ and it was through the unbroken skin of the feet that the larvæ gained entrance.

The PRESIDENT said he had found the disease among the miners in Cornwall; these men suffered from anæmia. They also had a pustular eruption on the hands and he thought it might be spread by this eruption. He agreed with Dr. Smith that infection could take place through the unbroken skin.

PSYCHOLOGICAL MEDICINE.

WEDNESDAY, JULY 27TH.

The *presidential address by Dr.* CHARLES A. MERCIER (London) dealt with the subject of

Criminal Responsibility and Degeneracy.

[illegible] -cier, there had been a difference [illegible] the professions of law and [illegible] was largely due to difference of aim. Thus the legal mind approached the question of criminal responsibility mainly with the object of protecting the community from wrong-doers, while the medical mind was apt to regard primarily the individual offender and the justice or hardship of the punishment inflicted on him, and was inclined to strive for the mitigation of punishment. But neither the protection of the community from wrong-doers nor the protection of individual wrong-doers from excessive punishment was the ultimate aim in dealing with criminals. Both of these were subsidiary to the attainment of a still more desirable end—the strengthening of the sense of responsibility throughout the whole community. In the bad old days, before Sir Samuel Romilly, the general sense of responsibility was not strengthened by savage punishment but weakened. The standard of morality was not higher but lower when 20 felons, men and women, were hanged at Tyburn every Monday morning; when 200, 300, 500 condemned prisoners were lying in Newgate at the same time under commuted sentence of death waiting for the ship to take them to Botany Bay; when children were hanged for petty offences; when, on the one hand, an innocent man could be hanged on the evidence of Jonathan Wild, and on the other, no weight of damning evidence could secure a conviction if there was some trumpery verbal flaw in the drafting of the indictment. The most important elements in punishment were discrimination and certainty of infliction and, in the circumstances referred to above, these elements were not only lamentably defective but appeared to be deliberately minimised. It was important to cultivate and to increase the sense of responsibility in all citizens, but this aim was defeated by the spread of the doctrine of degeneration as advocated by certain writers. Dr. Mercier combated and, indeed, ridiculed the use of the term degeneracy as popularly used at present. "If by degeneracy is meant a peculiar diathesis or variety of man, distinguishable from other men by 'stigmata,' that is, by peculiarities of structure, or function, or habit, that are inborn, that are constant in individuals that are so stigmatised, that mark off the degenerate from the normal man, then de- [illegible] exist, [illegible] nicious [illegible] Dr. M- [illegible] against the system of the housing, education, and treatment of criminals carried out at Elmira Reformatory and regarded the methods adopted there as an example of waste, of luxury, and of misapplied philanthropy. The criminals educated and trained there were provided with luxuries by which the wicked man was to be turned away from his wickedness But these luxuries "did not grow spontaneously nor did they fall like manna *from heaven. They were provided for the use and delight* of the criminal by the thrift, the labour, the self-denial of law-abiding men. If criminals and scoundrels of every order were thus to be pampered, what was to be done for the [illegible] -st, law-abiding citizen who saw [illegible] -ill-rewarded toil and privation, [illegible] -ortitude, no resting-place for his [illegible] the workhouse—that workhouse which was scorned and derided by the occupants of these comfortable reformatories?" Granting all that the fanatics of criminal pampering claimed for their results—"even granting that a certain small proportion of scoundrels might by a course of Turkish baths and lectures on English literature, and the study of Plato, as carried out at Elmira, be weaned for a time at least from a career of crime—was the game worth the candle?" And was it worth spending thousands of pounds of public money in turning a few criminals into indifferent citizens? He thought it was not. Dr. Mercier then proceeded to discuss the question of the punishment and responsibility of criminals from a medico-legal standpoint; dealing with "the legal question" was the *animus nocendi* or *scelerandi* present, was the act wilful, that was done with knowledge of the act and of its obvious consequences and with intention to bring about those consequences, and, finally, was insanity when present an exonerating factor or not? He thought that insanity was not necessarily an exonerating factor. When the personality of the wrong-doer was so affected by disease, said Dr. Mercier, that not only his will but his desires were also insane, then the case became extremely difficult to decide as regards the degree of responsibility to be attached and he thought that a mitigated punishment most nearly satisfied the ends of justice.

Following upon the above paper a communication received from Sir Herbert Stephen was read.

Sir HERBERT STEPHEN (London) wrote that the question whether or not there existed a "criminal neurosis" was a question not of law but of medicine. He followed the opinions he had heard expressed by Dr. H. Maudsley and Dr. Mercier that such a condition did not exist and if, in his judgment, the existence of such a neurosis was proved or shown to be decidedly probable he should allow medical evidence to be given to that effect, but should advise juries that that was evidence tending to prove the accused person to be guilty. He further would regard the condition of "criminal neurosis" in convicted offenders as a reason for depriving them of their liberty (to commit crime) for as long a period as possible, for the essential point to be apprehended in the proper legal treatment of insane criminals was that some criminals who are insane should nevertheless be treated as criminals, though it might frequently happen that their insanity should be considered a reason for mitigating the severity of their punishment. An epileptic who, in the course of a fit or in the state of unconsciousness following a fit, killed some one, generally a friend or lover and often in the presence of others, had no memory of the act or in a minority of cases had only a faint and clouded memory like the memory of a dream. Such a case ought to be treated merely medically and should suffer no punishment but should be restrained as a precaution against a recurrence of the epileptic attack. When a woman, generally soon after childbirth, killed her newly born child (by drowning or otherwise) she knew that she was killing the child and meant to kill it and did so because being passionately fond of it she had an insane obsession of mind to the effect that death was highly desirable for the child. When the mental obsession had passed off the woman remembered what she did and deeply regretted having done it. He did not consider mere punishment suitable for such cases as these but thought there should be a considerable period of enforced seclusion and submission to some form of discipline, because although the patient's knowledge of her act and of its nature was entirely overcome for the moment by the violence of her mental obsession it was never entirely abolished or suspended as in the case of the epileptic. A third class of cases included those in which the insane affection of the mind was a more remote cause of the crime than in the two previous classes. Here the patient in consequence of his morbid mental affection conceived a violent hostility towards some person. He then, in gratification of his hostility, proceeded to murder his victim, showing premeditation, care, and resolution in effecting the deed, and skill in [illegible] that th- [illegible] wrong, [illegible] be puni- [illegible] and the [illegible] himself to have suffered should not be counted in the least in exoneration of the immorality or the illegality of his act. Insane criminals belonging to this class ought to be punished. In some cases, though not very many, he thought the full penalty for the offence should follow the conviction exactly as if the offender were perfectly sane. In others where the extent of morbid delusion and insane behaviour appeared to be comparatively great he thought that the punishment should be mitigated. He included in this latter class the cases where mental disorder amounting to insanity was the original cause of criminal indulgence of the sexual passion, whether the resulting crime was murder or rape.

Mr. A. Douglas Cowburn (London) submitted that "wrong-doer" was too vague and indefinite, that distinction should be drawn between crimes, torts, breaches of contract, and mere moral obliquity. Crime on the one hand was an act or omission punished by society as a wrong against itself. Tort on the other was a wrong inflicted by a man on his fellow, not regarded as a wrong done to the State but as giving rise to a civil action for damages. This distinction was important. Assuming that by "wrong-doer" was meant a convicted criminal he objected to and repudiated the proposition that insanity did not of itself necessarily exonerate him from punishment. He thought that it should. Dr. Mercier had expressed his satisfaction with the answers of the judges in 1843. That was not the opinion of Lord Brampton and Lord Coleridge. Those answers had been repudiated by many States of America, by Italy, and even by Russia. He submitted that the only real, true test was that laid down by the State of New York, "No act done by a person in a state of insanity can be punished as an offence," and applied by the State of New Hampshire in the case of the State *v.* Jones (50 New Hampshire, 1892, p. 369, *et seq.*). This simply left to the jury as matters of fact whether the accused committed the crime in question and whether at the time he was suffering from any disease of the mind and left it there. The difference between mental health and mental disease was a scientific fact entirely within the purview of medicine and with the particular forms of insanity and its essential characteristics the law, as such, should have nothing to do. *Per contra*, responsibility (by which was meant liability to punishment) was a matter purely for the law, and if the law as voiced by the jury under the guidance of the judge did not determine who were to be punished it determined nothing. Juries did not understand difficult psychological matters or elaborate legal criteria and they probably paid no attention to either. They were simple men, perhaps, but very conscientious; they convicted if they thought that the act was committed by an ordinary criminal and they acquitted if they thought the agent was insane. He submitted that if the law of England would follow the American example and would hold that no man should be held criminally accountable for an act which was the offspring of mental disease it would be more in accordance with the dictates of common sense and humanity and would be more likely to solve the difficulties which arise at present. If it was objected that this amounted to no definition at all, that it was too vague, too indefinite, to be accepted he would submit that it was far better in a region where there were so much difficulty and uncertainty that the law should not define at all rather than make a bad definition which, while contrary to its purpose, would be perpetuated by its authority. *Omnis definitio in jure periculosa* was especially true of this subject. They wanted, not "definitions" of insanity nor "criteria" of responsibility, but recognition of the only humane principle, that no man should be criminally accountable for an act which was the offspring of mental disease.

Dr. T. Claye Shaw (London) said that there were many degenerate people who were more liable and prone to commit crimes than others. He traversed the statement that insanity did not exonerate the wrong-doer from punishment or that the *animus nocendi* settled the question between the lunatic and the criminal as regards responsibility.

Mr. H. Havelock Ellis (London) said (in a written communication which he forwarded) that his standpoint was substantially the same as that of Aschaffenburg in his recent book, "Das Verbrechen und seine Bekämpfung." From the strictly medical point of view we were not entitled to use the word "responsibility." Responsibility was not a medical conception; it was a legal and metaphysical conception. It was the lawyer's business to determine responsibility as nearly as he could in accordance with the facts ascertained by the medical man. It was on this basis alone that the existing confusion could be brought to an end.

Dr. G. H. Savage (London) pointed out that degeneracy might and did produce deviations of a character opposite to one another, differing widely from the healthy or normal standard; thus dwarfism and gigantism were both manifestations of degeneracy. Though some delinquents were more mad than bad and others more bad than mad, and delinquents ought to be punished, yet if guided by legal principle they must be, if insane, not punishable. He did not agree with all that Sir Herbert Stephen had said as to the third class of persons who, though insane, yet knew the quality of their acts and so should be punished.

Dr. David Yellowlees (Glasgow) said that it was impossible to draw a sharp line between sanity and insanity; that humanity stood on a great slope, on the top of which were sane, reasonable, stable, self-guiding persons; at the bottom were the idiots and the chronic dements; and in the intermediate regions of the slope were the subjects of mental and moral defect and disorder of varying degrees. Whatever the law might say these persons on the slope must be dealt with specially since they were not like normal men and when they committed crime they should be judged more leniently and punished less severely if at all, "according to their position on the slope" of mental development.

Dr. G. Fielding Blandford (London) said that degeneracy was often due to environment and young children of degenerate and criminal character might, by living and being brought up in better surroundings, become well-behaved citizens. In the case of partial or less severe forms of insanity a mitigated responsibility should be attached to criminal deeds committed by the patient.

Mr. Conolly Norman (Dublin) said that it seemed to him there was a tendency to "obsession" both on the part of the physicians and the lawyers, one side of the house being oppressed with the fear lest those of unsound mind might be unjustly and cruelly punished, the other lest wicked criminals should escape their deserts through the machinations of foolish medical men. As to the question of responsibility in court he held that that was not a question for the physician and pointed out that Griesinger long ago laid down the maxim and acted upon it when called upon for his opinion on this point.

Dr. Ernest W. White (Dartford) said that most physicians were agreed that insanity should exonerate a criminal from penal servitude but not from going to a criminal lunatic asylum where he would be subject to moral discipline and surroundings not congenial to his nature and to a deprivation of freedom nearly allied to punishment. Probably nearly all the insane other than dements and aments (idiots) had some knowledge of right and wrong and could be controlled accordingly. There were degrees of responsibility in connexion with the insane which ought to have due consideration. He recognised that the graduated slope described by Dr. Yellowlees did exist and not a precipice dividing mankind into the sane and the insane and that while sanity reigned at the summit of the slope insanity lay at its base and on its sides.

Dr. Robert Jones (Claybury) said that the evolution of human thought and conduct in regard to punishment of wrong-doers showed stages of development: first, the primitive legal aspect of retribution in kind—an eye for an eye, a tooth for a tooth. With the progress of human society and the growth of sympathy and of altruism consideration for the individual arose and the protection of society was combined with thoughts for the disciplinary and temporary nature of punishment to be meted out to offenders. Though the sane mind was constituted after a plan or pattern which was approximated by the insane mind there were states of mind in which, owing to the predominance of delusions, the insane criminal could not judge of the nature of his actions and was not influenced by motives which were adequate to influence normal minds. Just as there were grades and varieties of colour-blindness or of deafness, so, he maintained, were there degrees of impairment of thought and reason, varying from slight abnormality to complete dementia, so that responsibility was attenuated and punishment should be mitigated. Insanity exonerated the patient from punishment in accordance with the degree and character of the mental alienation or disorder occurring at the time and he certainly dissented from the conclusion of the President that insanity does not necessarily exonerate from punishment.

Dr. G. E. Shuttleworth (Richmond) said that idiots occasionally committed murders or crimes of the most senseless and stupid character. He believed that congenital moral imbeciles were born into the world, children whom the older theology would regard as endowed with a "double dose of original sin." Punishment was probably thrown away upon them but there were other children whose moral defects were less marked and who were more capable of being influenced by environment and by appropriate punishment.

Dr. Mercier then briefly replied.

Lantern Demonstration on General Paralysis.

Dr. David Orr (Prestwich) and Dr. R. G. Rows

(Whittingham) gave a lantern demonstration with slides showing photo micrographs of the Degenerative Lesions occurring in the Posterior Columns and Roots of the Spinal Cord in General Paralysis, with remarks on the point of origin of the lesions in tabes dorsalis It was pointed out that the distribution of the lesion in its earlier stages and the anatomical changes in the nerves as revealed by Marchi s method supported the theory that the posterior nerve roots were particularly vulnerable at and near their point of entry into the spinal cord and that a [illegible] blood was the probable [illegible] question But why one set [illegible] the posterior roots should [illegible] the rest underwent degeneration was a problem that still awaited solution This brought the day s proceedings to a close

PHYSIOLOGY

WEDNESDAY, JULY 27TH

A paper by Dr A P BEDDARD (London) and Dr E I SPRIGGS (London) on

Some Points in the Metabolism of Diabetes with Reference to Present day Treatment

was read by Dr Spriggs and showed that the sudden withdrawal of carbohydrates from the diet of a diabetic patient was wont to be followed by symptoms of nausea, vomiting, weakness, loss of weight, and the odour of acetone in the breath, and that the metabolic changes as determined by daily estimation of the nitrogen ammonia sugar acidity, and oxybuty [illegible] is those of c[illegible] n deprivation [illegible] The most prominent change in the urine was a rapid rise in the proportion of nitrogen secreted as ammonia —e g, in one case from 7 to 29 per cent The blood also became less alkaline and contained less carbon dioxide The noxious material which gave rise to these symptoms of acid poisoning could hardly be derived from carbohydrates since the removal of carbohydrates was followed by its increase Administration of large doses of sodium bicarbonate caused a general improvement in the condition of the patient, disappearance of the smell of acetone in the breath, and diminution of the ferric chloride reaction of the urine, although there was no marked change in the amount of sugar excreted in the urine The ferric chloride reaction and the weight of the patient supplied much more trustworthy evidence of his condition than the amount of sugar in the urine It was advisable when carbohydrates were removed from the diet of a diabetic patient to give large doses of bicarbonate of sodium until the urine became neutral but it was necessary to watch for possible disturbances of digestion and œdema produced by the alkali

Dr W LEONARD BRADDON (Seremban, Malay Peninsula) read a paper on

A New Method of Staining Red Blood Corpuscles

By using a solution containing ½ per cent of ordinary methylene blue and 1 per cent of potassium citrate structures which he had called "mycoid bodies" could frequently be demonstrated inside red blood corpuscles It was, however essential that the blood should not have been previously dried as in the ordinary method of staining blood films The appearance of these bodies suggested that they were living organisms such as myxomycetes, but they might conceivably be nothing more than coagula They occurred in small numbers of corpuscles in most apparently healthy animals but they were never present in large number except in illness

A paper by Dr F GRIFFITH (Liverpool) and Dr W B WARRINGTON (Liverpool) on

The Varieties of the Cells of the Spinal Ganglia and their Relationship to Axons of Different Distribution

showed that Nissl s method had in the hands of Lugaro shown five different types of cells in the spinal ganglia Dr Griffith and Dr Warrington had by section of various nerves attempted to ascertain the peripheral connexion of these different nerve cells After removal of the stellate ganglion they observed changes in cells of Lugaro s "dark obscure type in the first five thoracic spinal ganglia, these cells having a diameter of 30μ to 40μ The axons divided were probably afferent nerves from the heart and lungs and it was interesting to note that since the afferent fibres of the splanchnic nerves arose from regions as high up as the fourth thoracic segment the same segment of the cord supplied both abdominal and thoracic viscera, and thus the observed overlapping of sensory areas of referred pain in diseases of the stomach and of the lungs could be accounted for After section of the "hamstring nerve' chromatolysis was detected in the sixth, seventh, and eighth thoracic spinal ganglia, the changes occurring principally in the largest cells (over 80μ) but also in smaller cells down to 30μ The nerves to the muscle spindles appeared therefore to arise from the largest cells—those of Lugaro s ' large clear type After section of the internal saphenous nerve there was chromatolysis in cells 28μ—71 5μ in diameter found in the sixth lumbar spinal ganglion, most of them belonging to the obscure type ' Coarsely granular cells and cells of the smallest type, less than 30μ across, never showed chromatolysis Donaldson's enumeration of nerve cells of spinal ganglia pointed to the latter as immature cells not yet possessed of an axon

Dr ROBERT KENNEDY (Glasgow) read a paper on

The Histological Changes occurring in Ununited Divided Nerves

The changes in the peripheral portion of a nerve severed from its central connexions consisted of (1) pigmentation and eventual complete absorption of the old axis cylinders and their myelin sheaths, leucocytes and connective tissue cells invading the nerve, and (2) almost simultaneously with the beginning of the former process proliferation of the cells situated between the sheath of Schwann and the medullary sheath Study of the later changes occurring in the peripheral segment left no doubt that the chief function of the proliferation of the neurilemma cells was a regenerative one and that the cells in question gave rise to new nerve fibres This regeneration progressed only up to a certain point so long as the peripheral portion of the divided nerve remained isolated from the central end but reached its highest point in those circumstances within a few weeks It could then readily be demonstrated by Stroebe s method that fine nerve fibres were present, possessing an axis cylinder surrounded by protoplasm in which were deposited fine drops of myelin, with a delicate sheath of Schwann and well marked nodes of Ranvier When the peripheral segment was at an early stage reunited to the central end of the divided nerve precisely the same changes occurred, the only difference being that the young nerve fibre progressed rapidly to adult dimensions All the above changes occurred in an excised [illegible] e subcutaneous [illegible] ter six months [illegible] d little further development to be capable of conduction was shown by the early return of sensation after secondary suture He had by careful examination of 40 such cases observed return of sensitiveness to the prick of a needle within one or two days of the secondary suture even though the nerves had been divided for long periods—e g in one case after 18 months—and the analgesia before the operation had been absolute In the remaining part of his paper Dr Kennedy described the structure of the sciatic nerve of a leg amputated at the knee 25 years previously and stated that fine nerve fibres were present in abnormal numbers This increased proportion of small nerve fibres was best explained on Mayer s view that degeneration and regeneration were constantly taking place as a normal process in nerves some of the regenerated nerves *having in the absence of their* normal peripheral connexions to acquire their normal dimensions

Professor FRANCIS GOTCH (Oxford), in discussing Dr Kennedy s observations said that they appeared to prove that axon formation of the type shown in the tail of the lizard &c could take place in mammals, but it still appeared extremely doubtful whether axons possessing the true nerve properties of excitability and conductivity could be thus formed in higher animals Halliburton and Mott had shown that a second section of the nerve caused degeneration in all the fine nerve fibres present in the peripheral part of the previously divided nerve, a result which seemed to show that the fine fibres had somehow entered the peripheral fragment of the nerve by sprouts from the central end He also doubted the genuineness of the so called immediate recovery of sensation within a few days of secondary suture, for he had been struck by the fact that accompanying the apparent hyperæsthesia to such tests as needle-pricks there was absolute anæsthesia to the far more sensitive test of stroking the hairs over the affected region. Head's remarkable investigations on himself showed plainly the [illegible] the stimulus so that it should not aff[illegible] marginal zone of the anæsthetic region.

Professor WESLEY MILLS (Montreal) called attention to the value of Bielschowsky's method of demonstrating the presence of axons, as also did Dr. WARRINGTON.

Professor W. H. THOMPSON (Dublin) thought that Dr. Kennedy had conclusively demonstrated the formation of structurally almost perfect nerve fibres in completely severed portions of nerve trunks.

Dr. H. M. VERNON (Oxford) read a paper on

The Protective Value of Proteids and their Decomposition-products on Trypsin.

The trypsin solution employed lost 56 per cent. of its proteolytic activity during exposure to the action of 0·4 per cent. sodium carbonate solution for one hour. In the presence of 1 per cent. of proteid it lost only 27 per cent., with 2 per cent. proteid only 13 per cent., and with 4 per cent. proteid only 7 per cent. Egg albumen had itself a marked antitryptic power and was therefore not employed for the above purpose. The protective value of the hydration products of proteids depended entirely upon their power of neutralising the sodium carbonate solution.

ANATOMY.

WEDNESDAY, JULY 27TH.

Professor A. THOMSON (Oxford), President of the section, occupied the chair and there was a very good attendance. After a few words of welcome from the President,

Dr. C. J. PATTEN (Sheffield) read a paper in which he suggested

A New Method of Mounting Anatomical Preparations for Museum and Dissecting-room Purposes.

He thought that the methods at present in vogue of mounting wet specimens were not wholly satisfactory and what was really wanted was a method of mounting in such a way that specimens could be readily removed from, and replaced in, the preserving fluid without the slightest detriment. To this end he suggested the following method. Four pieces of wood were taken and tacked together in the form of a frame which was then laid down on a perfectly clean sheet of plate-glass well oiled. Plaster-of-Paris, prepared by mixing 27 parts of the plaster with 22 parts of water, was then poured into the frame until the area inclosed by it was completely filled. A second sheet of plate-glass, well cleaned and oiled, was then quickly laid on the plaster. In a short time the glass was taken off and a slab of plaster-of-Paris, smooth and highly polished on both sides, could then be removed from the frame. The specimen to be mounted was placed on the slab and glass rods with pointed ends were employed to fix it and it was important that the rods should be fixed before the plaster had set quite hard. The specimen was then placed in an oblong museum jar and covered with a lid. Amongst the advantages resulting from the employment of this method Dr. Patten enumerated the following: (1) the specimen could be taken out and replaced at any time; (2) the specimen need not be handled; (3) the specimen was very suitably arranged for photographic purposes; and (4) it was easily re-tinted and re-lettered. He also thought that, in addition, the drawbacks of all methods of mounting wet specimens—viz., the discolouration of the preserving fluid and the collection of sediment—could be most easily overcome by his arrangement of an easily removeable lid which allowed of the entire vessel being periodically rinsed out. Such specimens always looked beautifully clean and bright.

The PRESIDENT showed in support of this method a frozen section which he had mounted some time ago on a slab of plaster-of-Paris. The great advantage was that the whole thing, specimen and slab, could be removed from the preserving fluid and that both sides of the section could be readily examined.

Dr. T. H. BRYCE (Glasgow) gave a lantern demonstration illustrating his researches on the [illegible]

Histogenesis of the Blood in Larval Forms of Lepidosiren.

He showed that in the blood and tissues free white elements of various forms were found at an early period and he classified them in three groups: (1) the mononuclear leucocyte (leucoblast) which might be large or small; (2) the eosinophile leucocyte (erythroblast); and (3) the polymorphonuclear form, of variable size and either hyaline or granular. With regard to the origin of these elements, Dr. Bryce pointed out that larval forms of lepidosiren had no bone marrow and that the liver had no place in the formation of the blood. All the varieties arose *in situ* from mesenchymatous elements first in the splanchnic mesenchyme and afterwards in the mesenchymatous tissue around the pronephric duct and mesonephric tubules. In lepidosiren the thymus had no share in the first origin of the leucocytes. [illegible] contained lymphoid elements the spleen a[illegible] of forming leucocytes and this, again, was preceded in that function by the specialised tracts of mesenchymatous tissue referred to above. Dr. Bryce's specimens clearly showed that at a very early stage at a spot on the inner side of the mass of yelk cells, and long before there was any spleen or thymus, a mass of cells became marked off from the general mass. A little later, at a time which he called the "critical stage," the mass of cells was cut off from the yelk cells. They contained various forms of leucocytes and becoming converted into wandering cells eventually became the leucocytes. In his later slides Dr. Bryce showed the formation of the spleen and in the spaces of the organ young white and young red corpuscles, and lastly he showed the formation of the thymus in which only a few leucocytes seemed to be found.

Professor A. ROBINSON (London) asked for further information concerning the localisation of leucocyte formation and also for Dr. Bryce's differentiation of mesenchyme from mesoderm.

Professor F. KIEBEL (Freiburg), referring to his own work and that of his pupils, Professor Tonkoff of St. Petersburg and Dr. Piper of Berlin, said that in lower and higher vertebrates they had evidence of the origin of the blood from mesenchymatous structures and he was pleased that the interesting investigation of Dr. Bryce on lepidosiren on the same lines seemed to be confirmed. The question of the origin of leucocytes in the thymus he was now working at and, so far as he had gone, he could not come to a confirmation of Dr. Bryce's results. At the same time, seeing that his own investigations were unfinished, he preferred not to give any decided opinion.

In reply to Professor ROBINSON, Dr. BRYCE explained that the tracts in which the leucocytes were found developing were localised. The general mesenchymatous tissue did not show the same phenomena and in regard to his results, while they held good only for the form under study, they were to be considered as a contribution to the establishment of a general theory of the leucocytes.

Giants and Dwarfs.

The remaining part of the morning was devoted to a discussion on Giants and Dwarfs. This was introduced by Professor D. J. CUNNINGHAM (Edinburgh) who proceeded to give a most interesting account of the skeleton of the Irish giant Cornelius Magrath, which had been in the possession of Trinity College, Dublin, for close upon one and a half centuries. There was no museum specimen in Ireland better known or one which had created a wider interest. On account of his great height, references to Magrath were found in almost every work on anthropology in which the human stature was discussed. Yet his reputation in this respect rested upon an altogether fictitious basis, inasmuch as Magrath could not claim to first rank as a giant. Most contradictory statements had been made in regard to his height. Humphry gave 8 feet 6 inches, Sternberg 8 feet 5 inches, Wood 7 feet 9 inches, and Topinard 7 feet 4 inches. There was, however, only one record of measurement taken during Magrath's lifetime by a competent and trustworthy observer and this was in Florence. Professor Bianchi after a most careful series of measurements made him out to be 7 feet 5 inches. This did not quite correspond with the height of the skeleton in Dublin which was 7 feet 2½ inches, but the discrepancy could be explained by the facts that the skeleton was not well put together and that it had lost height in the process. Professor Cu[illegible] giants [illegible] made of history and reminde[illegible] in earlier records were [illegible] eight, no matter how great or [illegible] d impossible. It might be said that the advertised heights of giants were nearly always too high and he was doubtful if there was any authentic record of a giant over 8 feet 2 inches or 8 feet 3 inches, though he did not regard this as the limit of stature. He showed slides of Wehde, a giantess who was said to be 8 feet 4½ inches in height, and of Winkelmeyer, a giant who was said to be 8 feet 6½ inches, but Virchow, who measured the giant most carefully, found that he was 7 feet 5⅝ inches. Slides were next shown illustrating the osteology of Magrath, which indicated that he suffered from acromegaly in its most pronounced form. And nowadays the leading interest attached to giantism was to a large extent centred in the relation which it presented to that disease. That both giantism and acromegaly were morbid processes there could be no doubt, but the precise relation which existed between the two conditions was the subject of much discussion. More than 13 cases of giants who were acromegalic were now on record. The view held in most general favour at present regarded giantism and acromegaly as due to the same morbid process, the results differing merely according to the period of incidence of the disease. If the morbid process occurred in a child or young person before union of the epiphyses a giant resulted, whereas if it occurred in an adult after the period of general growth had stopped acromegaly resulted. Meige had pointed out that acromegaly never preceded giantism and that in 50 per cent. of giants acromegaly followed.

Professor B. C. A. **Windle** (Birmingham) said that dwarfishness might be produced by various causes, being pathological or teratological, and to make our present distinctions clear he [illegible] ation; pathological drawfs, [illegible] (very rare), cretinoid, and [illegible] achondroplasic. Many dwarfs undoubtedly belonged to the latter class and the condition was also met with amongst animals and could be perpetuated by breeding, as, for example, the dachshund and the Basset pig. Teratological dwarfs were phocomelic where parts of the limbs were absent, micromelic where limbs were complete but unduly small, and nanosomes (or true dwarfs) which might be primordial (sexual)—i.e., small men and women; or infantile (asexual)—i.e., permanent children.

Mr. **Hastings Gilford** (Reading) regarded both dwarfism and giantism of marked degree as almost necessarily a sign of disease or malformation and such cases were, in reality, not in the domain of pure anatomy but belonged to pathology. He gave a most interesting demonstration of actual cases, illustrating the main types of dwarfs due to disease or malformation. In none of these could he trace the influence of syphilis, cretinism, congenital heart disease, or any other disorder. One was a species of infantilism, a defect not only of growth but also of development. This form of infantilism had been termed "ateleiosis," for those who were so affected seemed never to arrive at perfection. Another form of dwarfism exhibited characters of infantilism, premature old age or senilism, and abnormal development. In none of the conditions could the cause be determined. Mr. Gilford thought that there was reason to believe that the pituitary body was the seat of the disease and Dr. Woods Hutchinson had found actual disease of this body in one case, though it was apparently not of the same type as those to which he had referred.

Dr. G. A. **Gibson** (Edinburgh) supported the previous speakers and said that he regarded giantism as bound up in some way with acromegaly. He showed skiagrams of a case of this disease beginning at 19 years of age and he thought that the pituitary body might be regarded as a regulator of growth in some way.

Professor A. F. **Dixon** (Dublin) brought out an interesting association between the pituitary body and the facial bones affected in acromegalic disease. As was well known the pituitary body developed partly from the neural tube and partly from the buccal cavity. When the body was diseased, as in acromegaly, there was a remarkable selection of the facial bones in such a way that those developed as membranous bones in connexion with the primitive mouth or [illegible] ere were [illegible] those in [illegible] t and he referred to certain examples of great stature in which the lower extremities only were involved, a condition which was probably due to delayed union of the epiphyses and diaphyses of the long bones.

Dr. **Gustav Mann** (Oxford) suggested that the condition of the sympathetic nervous system *ought to be studied* in connexion with abnormal growth, inasmuch as removal of the superior cervical ganglion in newly born animals produced overgrowth of the head and ears on the same side as that in which the ganglion had been removed.

Dr. R. **Gladstone** (London) agreed with this and suggested that the enlargement of the pituitary gland in acromegaly and some forms of giantism was possibly secondary to a primary affection of the sympathetic system, and might perhaps be compared with hypertrophy of the thyroid gland in exophthalmic goitre.

Professor **Anderson** agreed that the evidence went to show that many of the so-called giants and dwarfs were pathological and thought that the condition was associated with a transfer of ossific matter from one place to some other.

Dr. **Patten** in support of Dr. **Thompson** mentioned a skeleton which he had described of an adult in which the limb bones were very long and heavy but in which there were no signs of acromegaly.

Finally, Professor J. **Symington** (Belfast) agreed with the pathological view of giantism and said that there were very few authenticated examples of individuals who had deviated markedly from the common standard, either one way or the other, that were really healthy.

PATHOLOGY.

WEDNESDAY, JULY 27TH.

The proceedings of the section were opened by the **President**, Dr. **James Ritchie**, who took

Immunity

for the subject of his address with the object of presenting a general review of the position of our knowledge in this branch of experimental research, pointing out that a general consideration of ascertained facts was rendered necessary owing to the divergent character of the studies, ranging from physical chemistry to hæmatology, now being prosecuted by different workers in the attempt to elucidate the problems involved. After paying an appreciative tribute to the genius of Ehrlich, whose theories of immunity, though promulgated some six years ago, still dominated the whole situation, Dr. Ritchie stated the main points for consideration as: (1) the natural immunity observed in certain circumstances to exist towards disease; (2) the artificially acquired immunity which came about in disease contracted under what might be called natural conditions of infection; and (3) the relation of those conditions to recovery in any case of infectious disease. The solid basis of facts already arrived at regarding the process of immunisation was briefly summed up. Certain of the effects of some bacteria, and most of the effects of other bacteria, could be traced to extremely soluble poisons of unknown composition and which frequently possessed a selective action on special tissues and when injected into the body of a susceptible animal rapidly disappeared from the circulatory fluids, probably in consequence of their fixation in susceptible cells to which they sometimes travelled by special paths. By methods of immunisation an almost limitless degree of immunity could be developed in a sensitive animal, associated with the appearance in the serum of that animal of a "specific" substance capable of neutralising that toxin which stimulated its genesis. Further, that the neutralisation of toxin by antitoxin was of the nature of a chemical union but that such union was dissociable. The elaboration of soluble toxin was not, however, a universal characteristic of bacteria and in the case of most it was necessary, not only to neutralise poisons, but also to destroy the bacteria themselves if the animal body was to escape destruction. So far as concerned highly immunised animals it might be stated that the destruction of the bacteria was associated with the presence in the serum of the immune animal of two substances—a thermo-labile "complement" normally occurring in the animal species involved and a thermo-stable "immune body," specific in character and *probably entirely absent* in normal serum and which would act deleteriously only on the protoplasm which stimulated its formation. The reactions of these two substances on one another and on the bacteria to be destroyed were of a chemical nature and analogous to the interaction of toxin and antitoxin. The view that these bodies did not exist apart from cells *in vivo*, and the results of Walker, which strongly point to the leucocytes as the source of the complement, also the contention *as to coincident and co-related cytolysis* associated with extra-cellular destruction of bacteria, were commented upon. Contrasting the infective with the toxin-producing bacteria it was pointed out that though we were practically certain that the presence of toxin in the animal body stimulated the production of atitoxin we did not know what portion of bacterial protoplasm stimulated the production of bactericidal substances. Dr. Ritchie, still speaking of the infective bacteria, remarked on the inadequate importance attaching to the metabolic aspects of the accompanying fever as compared with those dealing with the disturbances of heat regulation and suggested that part of the increased metabolism associated with infective fever might be the expression of work done by cells actively engaged in operating on the invading bacteria. Next the part played by persons in the production of the general effects caused by different infective bacteria was considered and it was pointed out that these poisons were for the most part intracellular and were probably derived from the breaking up of bacterial protoplasm which followed on death both in cultures and in the living animal and were responsible for what might be termed the non-specific effects of infective bacteria. Mention was made of the experiments of Pfeiffer and Kolle supporting the thesis that in the case of the infective bacteria the intracellular toxins which produced the pathogenic effects were not concerned in the production of the immunity which could be developed against these bacteria, for by appropriate dosage an immune animal could be made to exhibit the capacity of killing all the bacteria injected into it, and yet then succumb to the effects of the toxins which the death of the bacteria liberated from the bacterial protoplasm. After briefly commenting on the chemical reactions of toxin and antitoxin and contrasting the views of Ehrlich in explanation of the associated phenomena with those put forward by Arrhenius and Madsen, reference was made to what might be justly considered the three most important pieces of work bearing on immunity during the last year or so. First, that by Meyer and Ransome which established the fact that tetanus toxin reached the nerve cells by the path of the motor axones only, while their further observations went to show that antitoxin was conveyed to the nerve cells by the much slower route of the lymphatics, thus explaining the experimental fact that the injection of a very large excess of antitoxin would not protect an animal against the subsequent introduction of even a small amount of tetanus toxin into a motor nerve—observations which if confirmed destroyed the theory put forward by Ehrlich that antitoxin was formed in the nerve cells. Next, the work of Muir on the interaction of the constituents of hæmolytic sera which went to prove that when corpuscles were thoroughly saturated with immune body it was possible to dissociate a certain amount of immune body and cause it to become attached to fresh corpuscles, and further, that when red blood corpuscles were saturated with both immune body and with complement still some of the immune body but none of the complement could be dissociated from the combination—observations incompatible with the view that immune body formed a link between corpuscles and complement. Finally, the work of Wright and Douglas, which consisted in the elaboration of methods of precision which had enabled them to study the laws which govern the phenomenon of phagocytosis and to demonstrate the presence in the serum of a substance they termed "opsonin," whose function it was to unite with the bacteria, and by a process of sensitisation render them capable of ingestion by the phagocytes.

Dr. W. BULLOCH (London) was then called upon to read his paper on

The Cellular Aspects of Immunity.

Commencing with a chronological and historical review of the facts and theories dealing with the relationship of the body cells and fluids to the immunity problem, founded on a study of the original papers, Dr. Bulloch contrasted the sequence of the humoral and cellular theories of disease with a like sequence of theories as applied to immunity. He drew attention to the exhaustion theory of Pasteur which, based on observations of flask cultivations of the bacillus of fowl cholera, was insufficient to explain the process of immunisation as observed in the living animal, as it failed to account for the facts that immunity could be produced by means of the soluble products of bacteria and that the tissues of immune animals were well adapted as media for the growth of micro-organisms, although the possibility of certain forms of natural immunity owing their existence to absence of suitable nutritive pabulum was deserving of consideration in the light of Ehrlich's analogous suggestion of the absence of suitable receptors. Chauveau's retention theory, briefly discussed, was followed by a *résumé* of the zoological observations extending over many years, concerning the means employed by the infected host to resist microbial infection upon which Metchinkoff subsequently founded his phagocytic theory of immunity which might be briefly stated as the destruction of the virus in the interior of certain mesodermic cells by a process of digestion. In the meantime the humoral theory propounded by Buchner, based on the observations that the destruction of bacteria took place in cell-free serum *in vitro*, owing to the action of certain substances which he termed alexins, and that the bactericidal properties of the serum could be inhibited by heating to 56° C., found many supporters. The proposition that these alexins were derived from leucocytes led to researches that culminated in the partial fusion of the rival cellular and humoral theories, although the discovery of antitoxins at about this time raised the question of the site and mode of manufacture of anti-bodies. Denys and Havet showed by filtering dog's blood through paper that the serum was less bactericidal for bacillus coli than the blood and concluded that the leucocytes which were held back in the process of filtration were concerned in the formation of alexin, although they stated that cells and serum acted together in a manner varying with the species of animal and the nature of the virus. From this time on much research had been devoted to the question of the origin of the alexin and the question had been complicated by the fact that Buchner's alexin comprised two bodies—a complement (alexin proper) and an immune body. Metchnikoff considered that both these bodies were contained in certain phagocytic cells, the macrophages, and affirmed that plasma was alexin-free and contended that the alexic action was of the nature of a digestive process—a contention entirely negatived by the experiments of Grüber and others. Many observations were undertaken with a view to extracting alexin from the leucocytes but without success, although Dr. Bulloch by simultaneously measuring the amount of hæmolytic constituents on the one hand and the mono- and poly-nuclear leucocytes on the other, found that the appearance of the hæmolytic immune body in the serum was coincident with a rise in the number of mononuclear leucocytes, while by producing an artificial polynuclear pseudo-eosinophilia there was a coincident rise in the amount of complement. In the case of immune sera Pfeiffer, Wassermann, and others found that the main factory of anti-bodies was situated in the spleen, bone marrow, and lymph glands. From the mass of conflicting detail Dr. Bulloch concluded that the existence of alexins was undoubted but nothing certain was known of their origin; their existence in plasma was not definitely settled but the balance of opinion was in favour of their occurrence outside the cells; it was improbable that they acted like digestive ferments. Although highly probable, it was not proved that leucocytes secreted alexin, the diversity of opinion and the uncertainty being due to the complexity of the subject and defects in technique. Wright and others had shown that serum, whether normal or immune, was not bactericidal for the staphylococcus, using the term in its strict sense, and Dr. Bulloch had demonstrated the same fact with regard to the bacillus pyocyaneus; and in considering the conflicting claims of serum and cells in this connexion it must be questioned whether immunity was necessarily always antitoxic or bactericidal. The work of Wright and Douglas had shown that in phagocytosis a cardinal rôle was played by thermolabile substances, termed opsonins, present in the serum which had nothing in common with Buchner's alexins, and that during the process of active immunisation the opsonic value of the serum was definitely increased. Dr. Bulloch working with Mr. E. E. Aitken had confirmed the observations of Wright and Douglas on opsonic immunity and had found that the amount of opsonins in the serum could not be increased indefinitely as the result of inoculation, although opsonin was somewhat analogous to agglutinin. Further, serum contained a number of opsonins, each specific for given bacteria, and which could be removed in succession by saturation—results in harmony with the pleurimistic doctrines of Ehrlich. Thus, in addition to antitoxic and bactericidal immunity, there also existed opsonic immunity—a phenomenon corresponding largely to the phagocytosis of Metchnikoff.

Dr. GEORGES DREYER (Copenhagen) then read a paper by himself and Dr. A. J. JEX-BLAKE (Oxford) on

Agglutinins in Relation to Immunity.

The previous work of Nicolle and Joos was briefly reviewed and the generally accepted explanation of this phenomenon was stated as the combination of agglutinable substance contained within the bacteria themselves with agglutinin present in the serum, which combination, however, did not take place except in the presence of a salt. The influence of Ehrlich's side-chain theory upon [illegible] to explain the mode of action of [illegible] next considered and the work of [illegible] to. These authors described the agglutinins as being composed of a specific, labile, precipitating group and a more stable combining group; in the same way the bacteria were described as containing a labile agglutinophoric group and a [illegible] the formation [illegible] influence of [illegible] that these agglutinoids possessed so great an affinity for the bacterial agglutinable substance as to be able to prevent agglutination—in the presence of unchanged agglutinin even—by combining with the bacterial haptophores. Dr. Dreyer and Dr. Jex-Blake carried out a series of observations by testing from 22 to 24 hour-old broth cultures of bacillus coli, or cultures of similar age, on agar, emulsified in 0·85 per cent. salt solution made up to an arbitrarily chosen standard of opacity, against the agglutinating immune sera of rabbits and goats previously immunised against bacillus coli and other agglutinants. The experiments were carried out by placing 1·5 cubic centimetres of bacterial emulsion or bouillon culture of bacillus coli in each of 24 small test tubes, adding a quantity of agglutinant to each of tubes 1 to 23, gradually diminishing so that tube 1 contained 100 times as much as tube 23 and making the contents of each tube up to 2·5 cubic centimetres. Tube 24, containing only bacteria and salt solution, served as a control. The tubes were well shaken, then heated in a water bath at 37° C. for from one and a half to two hours, then the amount of agglutination was measured, the measurements being repeated after further 18 hours at room temperature when necessary. The measurements were made partly by Madsen's method—i.e., selecting as a standard a moderately agglutinated tube and comparing it with tubes of other series—and partly by determining the tube showing the minimum agglutination visible to the naked eye in each series. The results yielded by the two methods did not always agree and discrepancies were particularly noted in cases where the serum had been first treated by heat or chemical reagents, from which Dr. Dreyer and Dr. Jex-Blake argued that the reaction velocity of the chemical or physical processes resulting in the agglutination of bacteria was a very variable factor. The age of agar cultures had little influence upon the agglutinability of the bacteria, but broth cultures showed diminished agglutinability with increasing age, due to the presence of toxins which combined with the agglutinin and were precipitated by excess of it. Eisenberg and Volk in investigating compounds formed by bacteria and agglutinins, found that the absolute absorption of agglutinin by a constant quantity of bacteria increased with increasing quantities of agglutinin; while the coefficient of absorption—e g., the ratio of agglutinin absorbed by bacteria to agglutinin originally present—fell. Dr. Dreyer and Dr. Jex-Blake found, using the filtrate of a 19-day broth culture of bacillus coli, that with increasing amounts of agglutinin its absolute absorption by the bacterial products increased, but that the absorption coefficient remained the same. When investigating the action of heat on the agglutinability of bacteria they noted that heating up to 60° C. scarcely altered the agglutinability of coli emulsion, but heating to 70° C. and upwards considerably diminished it, the diminution, however, being less marked with old cultures, and instanced a 24-hour-old culture requiring 35 times as much agglutinin after heating to 100° C. to produce a similar result as was needed by the unheated culture, but with a 50-day-old heated culture only 3·6 times as much agglutinin was needed as by the unheated emulsion. The suggestion that the heating destroys the agglutinable substance of the bacteria was denied by Dr. Dreyer and Dr. Jex-Blake for their experiments showed that prolonged—from two to 13 hours—heating of the emulsion at 100° C. partially, or even entirely, restored its agglutinability, a phenomenon which they explained by assuming that the agglutinin-fixing body, which was dissolved out into the fluid during the early stages of the heating, was destroyed by prolongation of the heating process. They also suggested that change in bacterial surface tension might be involved. In a similar way Dr. Dreyer's experiments showed that megatheriolysin heated to 60° C. for 30 minutes had no effect on goat's blood but after heating to 100° C. for ten minutes two and a half volumes would produce a similar amount of hæmolysis as one volume of the unheated lysin, whilst the identity of the hæmolytic reaction in the two cases was proved by the inhibition of the phenomena by the addition of antimegatheriolysin. In discussing the influence of heat on agglutinin itself Dr. Dreyer and Dr. Jex-Blake showed that when immune serum was heated for half an hour at 65° C. half the agglutinating power appeared to be lost if the preparations were examined at the end of two hours at 37° C., but when examined after a further period of 18 hours at room temperature the destruction of agglutinin was seen to be *nil;* and, further, that the greater the dilution at which the serum was heated the greater was the apparent destruction of agglutinin, from which they argued that the "zone of inhibition"—i.e., the production of more marked agglutination when the serum was present in small quantities than when present in large quantities—was not a consequence of the conversion of agglutinin into agglutinoid as maintained by Eisenberg and Volk, but that the phenomenon might be explained, partly at any rate, by a slowing of the velocity of the agglutination reaction. The agglutination of bacillus coli and bacillus typhosus by acids was then briefly described and its peculiarities were noted. The reaction was indistinguishable both naked eye and microscopically from that [illegible] emulsions of bacillus [illegible] were readily agglut [illegible] cultivations with diffi [illegible] of the phenomenon was that it was produced either by relatively large or by relatively small amounts of acid but not by the intermedi [illegible] cence of the emulsion [illegible] mediate zone of inl [illegible] density of emulsion. The addition of free acid to bacterial emulsion [illegible] presence c [illegible] it to one-h [illegible] third, although each of these quantities of acid acting alone would produce marked agglutination. Caustic alkalies did not agglutinate bacterial emulsions but rendered it less agglutinable. Acting upon immune sera an alkali was more destructive than an acid, though in each case the destruction of agglutinin was less than it appeared, as could be proved by suitable neutralisation.

Dr. THOROLD MADSEN (Copenhagen) then gave his paper on

The Neutralisation of Lysins,

in which he first described and demonstrated Ehrlich's conception of diphtheria toxin as composed of a series of bodies—proto-toxin, deutero-toxin, trito-toxin, and toxin, differing in toxicity and also in avidity for the antitoxin, by graphic methods with the aid of the familiar "spectrum" and "stair-step" curve, basing his remarks on the concrete example of the complete neutralisation of 100 toxic units *in vitro* by a quantity of antitoxin to which the numerical value of 100 had been assigned and showing how this theory of the composition of the toxin was supported by the results of partial saturation experiments. Passing on to his own experiments on tetanolysin (the hæmolytic substance of tetano-toxin) it was shown that almost identical phenomena could be demonstrated by similar means but that if the antilysin was added in very small increments to the tetanolysin the neutralisation could be represented by a regular curve showing no trace of the stair steps which indicate the different components of the toxin. Contrasting the results thus obtained with those observed during the neutralisation of a strong base by a strong acid on the one hand and of a weak base by a weak acid on the other, the similarity of the hyperbolic curves produced during the neutralisation of tetanolysin by antitetanolysin and of ammonia by boric acid was noted, and it was found that the necessary data could be calculated in a corresponding manner by the use of formulæ deduced from the *law of mass action* (of Guldberg-Waage): the formula for toxin-antitoxin combinations being expressed as

$$\frac{\text{Free toxin.}}{\text{vol.}} \cdot \frac{\text{Free antitoxin}}{\text{vol.}} = \text{K} \frac{(\text{Toxin-antitoxin})^2}{\text{vol.}}$$

where K is the constant of dissociation, and indicating that one molecule of antitoxin combines with a constant amount of antitoxin (perhaps one molecule) to form two molecules of one or more combinations of toxin-antitoxin. This application of the established laws of physical chemistry to toxin-antitoxin combinations and their subsequent partial dissociation explained the long zone of neutralisation—the continued addition of antitoxin causing continued diminution but never absolute disappearance of the amount of free toxin. Dr. Madsen then detailed his observations on diphtheria toxin which showed after the perfection of his methods a perfectly satisfactory correspondence between calculated and observed values and yielded regular curves without any indication of the presence of prototoxoid, and the deduction from these observations was that there was no reason to consider the diphtheria toxin as so highly complex a body as Ehrlich described. In this connexion Dr. Madsen commented on the varying values of the dissociation constants, from the small diphtheria constant to the highly dissociated curve of the tetano-lysin constant. Dr. Madsen, in association with Walbum, carried out similar observations upon several other bodies—ricin, rennet, vibriolysin, staphylolysin, and streptolysin, and their anti-bodies—and obtained similar curves and a similar close agreement between observed and calculated values for the various combination, while Dr. Madsen, together with Dr. Noguchi, obtained identical results with cobra, crotalus, and mocassin venom in combination with their respective antivenins. Dr. Madsen then proceeded to discuss his observations in association with Noguchi and Walbum on the hæmolytic action of acids and alkalies, vibrio lysin, streptolysin, ox-blood hæmolysin, the agglutinating power of ricin, and mercuric chloride upon erythrocytes, typhoid and coli agglutinins, the precipitating action of egg albumin precipitin, &c., with regard to the rates of reaction and the relations to temperature, and showed that the formula $\frac{C^1}{C^2} = E\frac{M}{R}\frac{(T_1 - T_2)}{(T_1 - T_2)}$ held good, when C_1 and C_2 are the concentrations at the temperatures T_1 and T_2, E, the base for the natural logarithms, $\frac{M}{R}$ a constant and T_1 and T_2 the absolute temperatures. Dr. Madsen concluded his remarks by pointing out the application of the law of monomolecular reactions (cf. sugar inversion) to the attenuation of poisons by heat by means of the formula $\frac{d_x}{d_t} = K(A - x)$, where $A - x$ is the concentration of the toxin at the time t, K is a constant and A the concentration at the beginning of the experiment.

Professor S. H. C. MARTIN (London) next read his paper on

Snake Venom in Relation to Immunity.

Having remarked upon the extreme potency of some snake venoms—0·000025 gramme per kilogramme causing death in the rabbit—the author pointed out that so far all attempts to separate the toxic principle from the modified proteid in which it existed had been unsuccessful and at present the toxic principle must be regarded as a special grouping of a portion of the atoms in the complex venom proteid molecule, although the suggestion was put forward that it might be a side chain and might ultimately be capable of differentiation. Venoms were shown to be highly complex in composition when examined by biological methods, many containing one or more but not all of the following: fibrin ferment, proteolytic ferment; neurotoxin, with special affinity for the respiration centre; neurotoxin with special affinity for muscle nerve endings; various cytolysins; anti-bactericidal body; agglutinin for red blood cells, &c., and the rapidly fatal action of some venoms was due to the neurotoxin causing respiratory paralysis, while others by their fibrin ferment produced intravascular clotting. Years ago Professor Martin expressed a belief in the unity of constituents having similar physiological action although derived from different snakes. More recent observations, however, on the differentiation of these bodies by means of their combining reactions with various antisera led him to the conclusion that although there might be similarity of the toxophoric groups of these various bodies their haptophoric groups were dissimilar. The chief interest of the snake venoms, however, lay in the analogy existing between them and the toxins elaborated by some bacteria and the important part played by experiments on snake venom in the development of our knowledge of immunity. Early experiments in the preparation of therapeutic antiserum led Calmette to maintain that such were not specific but this view had not been supported by the observations of Professor Martin and others and Calmette had recently admitted the existence of neurotoxin and hæmorrhagin, and further that the antitoxic serum obtained as the result of injecting cobra venom was without action on hæmorrhagin, but that employing cobra venom and viper venom a polyvalent serum could be prepared. Professor Martin was unable to confirm this statement nor was it supported by the observations of Tidswell on the venom of Australian snakes. These observations and those of Lamb, Rogers, and others, showed that the various sera were highly but not absolutely specific and that neutralisation might sometimes be accomplished by means of greatly increased quantities of heterogeneous serum. The advantages of venoms over bacterial toxin in experimental work upon immunity being greater stability when in the dry state and also in solution, the fact that they withstand heating to 70°C. or even boiling without being destroyed and, finally, their hæmolytic properties which, permitting test-tube experiments, made for greater accuracy and precision. After briefly summarising the work of early observers on the antagonism between toxins and antitoxins, the work of Fraser on cobra venom and antivenene was quoted in support of the hypothesis that this antagonism was of the nature of a chemical reaction. Professor Martin then referred to experiments carried out in association with Cherry in which filtration through a porcelain filter candle choked with gelatin was employed to separate toxin from antitoxin, the larger size of the molecule of antitoxin preventing its passage through the filter, by which it was shown that some chemical relationship between toxin and antitoxin was apparent after the mixture had stood for half an hour, because the filtrates obtained from these mixtures were harmless to guinea-pigs, and the great molecular size and complexity of the toxin and antitoxin was held to explain the high velocity coefficient of the reactions involved. Repeating some experiments by Fraser Professor Martin had found that when simultaneously injecting venom and a neutralising dose of its antitoxin subcutaneously in different parts of the body 20 times greater dose of antitoxin was needed than when the venom was introduced subcutaneously and the antitoxin intravenously, pointing to the probability of the more rapid absorption and fixation by the cells of the toxin.

A further contribution to the study of this branch of immunity was then made by Dr. NOGUCHI who presented the result of his

Therapeutic Experiments with Anti-crotalus and Anti-mocassin Sera.

After referring to the specificity of anti-sera prepared for the venoms of the crotalus, mocassin, and cobra Dr. Noguchi showed that a given dose of anti-cobra serum protected against five minimal lethal doses of cobra venom, when tested on the guinea-pig, only one of water-mocassin venom, and was quite ineffective against crotalus venom; and, further, that a given quantity of anti-cobra serum neutralised two minimal hæmolytic doses of cobra hæmolysin *in vitro*, but had no anti-hæmolytic action against crotalus or mocassin hæmolysin and so on through the remainder of the cross actions; and, further, that there was no constant relation between antitoxic and anti-hæmolytic values of an antivenene; hence the standardisation of antitoxic power of a serum could be made by simple hæmolytic tests in vitro. Turning then to the subject proper of the paper, experiments were quoted to show that two minimal lethal doses of a crotalus venom injected intraperitoneally killed a guinea-pig four to five hours later, and of a mocassin venom three and a half to five hours, the symptoms being similar in each case. Series of guinea-pigs were taken, each injected with two minimal lethal doses of crotalus venom, and at intervals of an hour different animals were treated with various doses of anti-crotalus serum. It was then found that it was possible to save the animal even at the most critical stages of intoxication so long as the experimental animal was able to stand. Similar results were obtained with anti-mocassin serum. The results were well shown in a table, from which the following is taken, and demonstrated conclusively the high therapeutic value of these two antivenenes.

Anti-crotalus serum		Crotalus venom (2 m l d.)	Anti mocassin serum		Water mocassin venom (2 m l d)
Time	Dose.		Time	Dose.	
Control.		Death average time 4 hours 25 minutes	Control.		Average time—fours hours 21 minutes
1 hour	1 c.c	Recovered	1 hour	1 c.c.	Death delayed to ten hours
2 hours	1 c.c	Death delayed to six hours		2 c c.	Recovered
	2 c.c.	Recovered.	2 hours	2 c c.	Death delayed to 3½ hours
hours	1 c.c	Death delayed to five hours		4 c c	Recovered
	4 c c.	Recovered	3 hours	4 c.c.	Death delayed to four hours
4 hours	4 c.c	Death delayed to nine hours		8 c.c.	Recovered
	8 c c	Recovered.	4 hours	10 c.c.	Recovered

From the result of his experiments the author concluded that the action of antivenenes was highly if not strictly [illegible] was variable, and that the estimation of one constituent gave no indication of the strength of the other

Dr M A RUFFER (Alexandria) then gave his paper on

Hæmolytic and Hæmoso.ic Sera,

detailing experiments carried out in conjunction with Dr Crendiropoulo on the effects produced on the blood by the injection of urine and bile The word hæmosozin, it was explained was coined to obviate the use of the term anti hæmolysin while the term lysogen was employed by the author to denote any substance which when injected into the animal body gave rise to the production of a hæmolytic serum Fresh urine of man and of animals injected into rabbits stimulated the production well within a week of a [illegible] also [illegible] was [illegible] was completely inactivated by 120° C for a similar time, it did not dialyse readily and was destroyed by digestion with mineral acids (5 per cent hydrochloric acid) and by long contact with alcohol Lysogen was precipitated by alcohol and by ammonium sulphate and was probably not one of the substances hitherto isolate [illegible] Miss Amos had shown that neit [illegible] uric acid, xanthin, &c, were [illegible] also contained a hæmosozin w [illegible] quantity when the urine was heated to 100° C and was destroyed by exposure to 120° C for 30 minutes The similarity of the reactions of these two substances should not be taken as proof of identity, for lysogen was specific hæmosozin was not, and would neutralise the hæmolysin of any serum Experiments carried out with bile showed that the hæmolysis produced in vitro could not be attributed to bile salts only for after dialysis the salt free bile was still hæmolytic On the other hand, the ethereal extract of bile was hæmosozic, and so was normal serum when tested against bile of an animal of the same species Hæmo ozic sera produced by the injection of bile neutralised completely the hæmolysins present in the serum of animals injected with urine

The section was then adjourned till 2 45 P M On resuming the sitting in the afternoon

Professor ROBERT MUIR (Glasgow) followed with a paper on

Hæmolytic Sera in Relation to Immunity

in which his remarks were limited to a discussion of three questions First the nature of the combination of anti substances, next the constitution and mode of action of complements, and lastly the combining relationships of receptor, immune body and complement In considering the saturation phenomena of immune body and red corpuscles its similarity to the process of neutralisation of toxin by antitoxin was remarked and it was pointed out that the amount of immune body which enters into combination was not a fixed quantity but varied with the amount of immune body present and that the reaction was in fact, an example of mass action, similarly the combination of complement and anti complement followed the same physical laws and in both cases the combination was a reversible process With regard to the second question, the researches of the author confirmed Ehrlich s views, and it might be accepted that complement is analogous to toxin and like it possessed two chief atom groups—a combining or haptophore group and a toxic or zymotoxic group, and the opinion was expressed that the combination of *complement with red corpuscles treated with* immune body was a very firm one end that the saturation phenomena observed might be due in part to the presence of "complementoids analogous to 'toxoids Further, the author admitted the probability of the multiplicity of complements and agreed with Ehrlich that more than one complen [illegible] a given serum On the other har [illegible] immune body might have several [illegible] and might so take up several different complements The zymotoxic group was much more labile than the haptophore group and might be destroyed by heat while the latter persisted, the resulting body being a complementoid which injected into an animal of a different species from that supplying the serum stimulated the production of anticomplement Intact corpuscles even when treated with immune body were almost impervious to complementoid, but when the toxic action of complement had occurred complementoid readily entered into combination Turning to the question of variations of toxic activity as contrasted with the combining affinities, experiments were *quoted which led to the important conclusion that the* therapeutical efficiency of a bactericidal serum depended not only on the ready combination of the compliment concerned through the medium of the immune body, but the bacterium would be sensitive to the action of the toxophore group of the complement Referring to the combining affinities of receptor immune body, and complement, it was pointed out that Bodet s theory that the immune body rendered the living cell ensitive to the action of complement was insufficient to explain the observed phenomena, although from the fact that neither receptor nor immune body was capable of taking up complement when separate but did so when combined one of the first two sensitised the other to the combining affinity of complement still the process was undoubtedly a chemical combination of these three different molecules The author concluded by referring to some of his experiments which showed that from a combination of receptor and immune body fully saturated with complement (the excess being afterwards removed) immune body could still be dissociated and that it came off as immune body alone—a phenomenon which it was impossible to explain on the supposition that immune body was a link between the receptor and complement molecules

Dr A E WRIGHT (London) then discussed

Opsonins and their Relation to Immunity

Prefacing his remarks by a short historical survey of theories of immunity, Dr Wright deplored the existence of an incurable disease prevalent among scientific workers and characterised by the building up of complete pictures of proce ses under observation from inadequate facts eked out by vivid imaginations Passing on to the results of a study of the changes induced in the blood by the inoculation of typhoid vaccine he referred to the preliminary negative phase characterised by lo s of bactericidal power, followed by a positive phase in which bactericidal power was increased and quoted experiments which clearly showed that after inoculation with small doses the negative phase was slightly and the po itive phase well marked but the reverse was noted after inoculation with large doses The speaker in association with Captain S R Douglas, I M S had investigated the phenomena grouped under the name of phagocyto is by improved methods which they had devised for the purposes which moreover, enabled them to manipulate cells of the blood quite apart from the serum One of the first results of this work was to [illegible] rease of phagocytic [illegible] ines was due to [illegible] In particular one set of experiments quoted brought out the point very clearly When the phagocytic index was calculated by the methods described, and assuming A to be an individual treated with, say staphylococcus vaccine then (1) A s white blood cells three volumes + A s serum three volumes + staphylococcus emulsion one volume gave phagocytic index of 25 7, (2) control white blood cells three volumes + control serum three volumes + staphylococcus emulsion one volume gave phagocytic index of 13, (3) A's white blood cells two volumes + control serum three volumes + staphylococcus emulsion one volume gave phagocytic index of 13, and

(4) control white blood cells three volumes + A's serum three volumes + staphylococcus emulsion one volume, gave phagocytic index of 28·2. Further experiments showed that these results were due to the presence in A's serum of a substance which by its action on the bacteria rendered them an easy prey to the phagocytes and to this substance the name opsonin had been applied.

The meeting then adjourned at 4.30 P.M. and at 4.45 P.M. Lantern Demonstrations on Colour Photography were given by Mr. **SANGER SHEPHERD** (London) and Mr. **J. HALL-EDWARDS** (Birmingham) respectively.

OPHTHALMOLOGY.

WEDNESDAY, JULY 27TH.

This section met under the presidency of Mr. **R. W. DOYNE** (Oxford).

The **PRESIDENT** bade a welcome to the number of ophthalmologists from the United Kingdom, from outlying parts of the empire, from America, France, and Germany, who had signified their intention, in an extensive list of contributions set down for discussion, of aiding the advance of their science and art. He felt the intention already realised in part by the largeness of the gathering before him.

The **PRESIDENT** then called upon Mr. **R. MARCUS GUNN** (London) to open the discussion on

Retro-ocular Neuritis.

Mr. Gunn said that he should include in this category all cases which showed evidence of the optic nerve being impaired by an inflammatory affection behind the papilla. The evidence was mainly clinical and the diagnosis, for a time, might rest solely on the subjective symptoms. But ophthalmoscopic changes came to their aid, either early in the affection by the neuritis invading the papilla or after the lapse of some weeks by the optic disc becoming pale. In exceptional cases only did opportunities occur of examining the affected nerve and then nearly always long after the inflammatory stage had passed away. Put very broadly, he would include all cases in which there was evidence of the optic nerve being inflamed, apart from such as were generally recognised as papillitis. But they were confronted by two questions: (1) How were they to recognise a neuritis when the papilla presented a normal aspect? (2) How were they to differentiate between retro-ocular neuritis involving the papilla and a pure papillitis occurring without evidence of intracranial or other disease calculated to produce it? The reply must be that they were now dealing with a well-recognised clinical group of cases, associated with certain definite subjective symptoms—namely, rapid failure of vision, particularly affecting the macular area, often in one eye only, usually accompanied by pain and tenderness in the orbit. Other characters were impaired pupil reaction to light, an absence of early ophthalmoscopic changes, and a tendency to recovery. Slighter or anomalous forms might occur without these symptoms or conditions as an early descending optic neuritis, from an anterior basal meningitis, would in its earlier course simulate a retro-ocular neuritis. Very similar symptoms occurred in central retinal affections and the differential diagnosis was often difficult during the early stages; the prominent symptom was central visual failure in one eye and at first there were no definite ophthalmoscopic changes. The chief distinguishing feature in the retinal cases was the absence of associated pain; there was also sometimes micropsia, or a positive scotoma, with a history of recent exposure to excessive light. They did not usually get the late pallor of the optic disc, but frequently found œdema and round, pale, yellow spots in the macular region. In the early stages, so long as the diagnosis rested merely on subjective symptoms, retro-ocular neuritis was liable to be confused with functional amblyopia, but a careful examination of the character of the reaction of the pupil to light should always serve to distinguish between them. The reaction was invariably impaired when there was decided amblyopia from neuritis, while it remained normal in cases of functional origin. The amount of amblyopia varied greatly. There might be absolute blindness for a time in the most severe form. On the other hand, occasionally complaint was made of recent visual failure, even though the acuity was $\frac{6}{6}$ In slight cases the test-letters were read slowly, as there seemed to be a mist obscuring their outline; this was particularly evident on comparison with the other eye, for these slight forms were practically always uniocular. A relative colour scotoma at or near the fixation point could always be found in these mild cases. Visual acuity in retro-ocular neuritis was worse in a very bright light and excessive light led to further temporary deterioration, probably from the physiological degeneration so induced in the ill-nourished axis cylinders. Occasionally complaint was made of seeing objects as through a moving haze like that seen on a sunny day near the ground; this might possibly be explained by imperfect insulation of the axis cylinders, from breaking down of their medullary sheaths, a change which was known to occur *early in retro-ocular neuritis.* Besides loss of visual acuity there was a marked diminution in the light sense. A feature of retro-ocular neuritis was the rapidity of the visual failure; this was in contrast with the length of time that a papillitis might exist without the nerve function being affected, and with the usually gradual failure when it did occur in the latter. The visual failure in retro-ocular neuritis very frequently took the form of an absolute central scotoma, surrounded by an area in which the colours red and green were recognised imperfectly or not at all. This visual loss was due undoubtedly to interference with the conducting efficiency of the macular fibres, which from their predominance, both in size and action, and probably by reason of their nourishment by peripheral blood-vessels (Silcox) were liable to degenerations not so easily affecting the general mass of the optic nerve fibres. Pain was a feature of the condition; it was marked in one-third of the cases collected. It was either referred to the back of the eyeball or was elicited on pressing the globe backwards. It sometimes preceded alterations in visual acuity. Lastly, there was much more tendency to recovery, even in severe forms of retro-ocular neuritis, than would be expected, judging from experience of other optic nerve lesions. At the same time there were exceptional cases in which no recovery took place, and others where there was a liability to recurrence so that ultimately the visual result was disappointing. On such important points of etiology as the relation of age and sex to the disorder he had made careful examination in the 350 *cases which he had collected. Etiology was varied and often* obscure. Toxic amblyopias proper, as from tobacco, he excluded from the group under review. In one class he included inflammation communicated to the nerve from neighbouring structures. Cellulitis or periostitis in the orbit accounted for 40 cases; exposure to cold for 27; inflammation secondary to dental abscesses for 17; and sphenoidal sinus disease for 18. In a second class he put local manifestations of general disease; syphilitic disease (gumma), 16; and insular sclerosis, a large group of 51 cases. A third class included neuritic cases of toxic origin, chief among which ranked influenza with 27 cases; next gout, 22; and blood disorders, malaria, constipation, ptomaine poisoning, mental or traumatic shock, &c., 68. Whilst in no less than 55 cases the causation was obscure. In regard to sex and age, on the average of all cases men were slightly more affected than women—37 as against 31 ratio, but in primary cases the females were decidedly predominant, particularly in the decade from 20 to 30 years. In this period alone there were 77 primary cases, of which 48 were in women and 29 were in men. After the age of 40 years men were more affected. The differences, he thought, were accounted for by the greater risks of females during the period of pronounced sexual activity, and of men in later years from shock, gout, and arterial disease.

Mr. **G. A. BERRY** (Edinburgh) laid particular stress on the value of the light-difference sense as an indication of the existence of the disorder, the more so as he was inclined to doubt the certainty of ophthalmoscopic examination as *to the presence or absence of an actual neuritis. He agreed* that the cause of blindness was in the loss of conductivity of nerve fibres and a light-difference defect was the feature of loss of conductivity. Further, the scotomata were homogeneous which was not the case in tobacco amblyopia. The homogeneity indicated an affection of the nerve by pressure and by an equal pressure. He was struck by the relative infrequency of cold among the determining causes as noted by Mr. Gunn; he thought that the proportion should be much larger. In influenza cases he had noticed a coincident affection of other higher sense nerves, as indicated by loss of smell and taste.

Professor **UHTHOFF** (Breslau) showed drawings of sections of the optic nerve from several toxic cases. The histological features in these he held showed that the affection was primarily an interstitial neuritis; there were increase of the nerve septa from proliferation of the fibrous elements and similar changes in the vessel walls, there was no indication of a simple degeneration of the nerve fibres, any changes in them were rather secondary to the interstitial changes than a primary degeneration

Mr C **HIGGENS** (London) commented on the variability in objective symptoms as shown by a case due to a general meningitis in a young lady The right eye was first affected and became blind, the left was similarly lost later, yet at no time were there any ophthalmoscopic evidences Many of his colleagues had expressed the opinion that the blindness was the result of cerebral tumour, but after death no growth could be found but a general meningitis which had involved the optic nerves so that they were converted into fibrous bands from chiasma to globe, scarcely a trace of nerve fibres remained

Mr F **RICHARDSON CROSS** (Bristol) expressed his indebtedness to the valuable work done on this subject by Nettleship and Gunn The disorder was a peculiar one and in some senses illogical He looked upon it as an inflammatory condition of the optic nerve in which no evidence could be seen ophthalmoscopically, if such evidence could be seen he concluded that there was a papillitis and not a retro bulbar condition alone, if there were no objective symptoms it was difficult to say that the disease was present Yet, as Mr Gunn had said, the group was distinguished by clinical symptoms which made it almost certain that there was an affection of the optic nerve between the globe and optic foramen He relied most upon the perimeter for diagnosis for he found in the neuritis of the atrophic order peripheral contraction and absence of scotomata He showed charts of cases demonstrating these points

Professor **OLIVER** (Philadelphia) insisted upon the importance of the light-difference sense and upon perimetric tests of the macular field In his practice he found the use of small coloured pellets as test objects, as suggested by Abney, of greatest value

Dr A **HILL GRIFFITH** (Manchester) believed that a considerable number of cases in rheumatic and gouty people were caused by an inflammation of the fibrous tissue around the optic nerve entrance to the globe of a nature analogous to the episcleritis of the front of the eye He was unable to substantiate Mr Gunn's observation that the pupillary reaction was impaired

Mr E **NETTLESHIP** (London) agreed that the light-difference sense was of the greatest importance, even more so than examination of scotomata He believed with Mr G [illegible] o [illegible] is [illegible] stress had been laid on the influence of cold He did not mean "catching cold" but exposure to low temperatures for many hours

Dr G **VICTOR MILLER** (Stockton-on-Tees) also agreed upon the direct etiological connexion of cold and rheumatism with the affection He described cases which were of this order

Mr **GUNN**, in reply, said that he was fully in agreement with the views expressed as to the influence of cold If his figures—27 in 350—seemed unduly low it was because many which might have been included in the group were complicated by overlapping conditions which seemed more important, this overlapping of possible causes was a matter of much difficulty.

Professor **POULTON**, F R S, read a paper on

Conclusions as to Vision in Birds based upon a Consideration of Mimetic Colour and Pattern in Insects

Whether animals saw as we saw was a matter of greatest interest We could not prove that they saw red as we saw red, but we could go a long way to indicate that there was a similarity in the perception of similar structures A large number of protective devices had been noticed in insects, adaptations which we assumed protected by similitude to indifferent or obnoxious objects If we examined some of these imitative effects we should note a most extraordinary accuracy in the imitation not only in general form but in particular detail, not only in general colour but even to imitation of stripes shades, and minute stippling In the case of the butterflies of North India, which imitated dead leaves, he demonstrated that all those marks on the leaf—holes, discolouration from decay or fungus invasion, exposure of venation—which we recognised as characteristic of a dead leaf were most accurately reproduced on the wings of these insects by the arrangement of the wing scales Such marks as holes were reproduced in exactly the same manner as an artist would indicate them on the canvas and in a varied manner as it was intended to suggest that the hole was seen in the light or against it. All these precautions were for the purpose of deluding the hungry bird to pass over the fly as a worthless and indigestible dead leaf, hence it was reasonable to suppose that the bird saw those details which go to make up the appearance of a dead leaf just as well as we do Similarly he showed the exactitude with which the females of some edible insects imitated non edible or obnoxious insects, both in the general colour, or striping, and minute colour details of the wings, hence we might similarly conclude that birds saw colours with a distinctness equal to our perception of them The paper was illustrated by a large and splendid collection of insects which were subsequently exhibited in the museum, the demonstrations of Professor Poulton were greatly appreciated

Mr M M **MCHARDY** (London) read a paper on

The Maturation and Extraction of Senile Cataract.

He detailed his experiences extending over a period of nearly 20 years of the operation for maturation of cataract by trituration through the cornea after the method of Forster. Many hundred cases had been so treated When he first performed the operation on carefully selected cases he was delighted with its success Later, in applying it generally to unselected cases, he had not obtained such good results, but these imperfections of procedure were speedily removed and after a long and extensive experience he was confirmed in his estimation of the value of the method At first failure attended some 16 to 20 per cent, now only about 2 per cent, damage to the lens necessitating immediate removal occurred at first in 4 per cent, now the accident was almost eliminated, being under 1 per cent Iritis there was now little or none, probably owing to the more efficient precautions taken against it with the use of cocaine and atropine The early liability to loss of vitreous was gone The prime object of the operation was to get rid of the sticky healthy cortical matter of the lens which was often slow to mature by natural processes and which if not completely removed in extraction seriously delayed the restoration of sight Trituration so affected this cortex that it rapidly became converted into a non adhesive substance of bread-and milk consistency which could be wholly evacuated with the nucleus There was practically only one contra indication—the presence of posterior synechiæ indicative of old iritis He preferred a preliminary iridectomy to immediate iridectomy and extraction

Mr **HIGGENS** said he had given up the operation years ago The method might be of service in a few but not in the majority of cases Further, he refrained from doing iridectomy unless some unusual condition compelled The excuse for trituration, in his opinion, had disappeared with the advent of cocaine, since an efficient local anæsthetic had replaced the general anæsthetic or no anæsthetic of former times there was no necessity for hurry and time could be taken to secure the removal of all the lens matter at the *extraction*

Dr **GRIFFITH** said he had performed the operation a good many times in the last 18 years He found no harm resulting therefrom and he was not inclined to abandon the method It was possible that these cases would have done equally well without the preliminary iridectomy and trituration, yet he felt happier in seeing the disappearance of all the clear cortical matter before operating

Dr J **LATHAM THOMPSON** (Cardiff) remarked on a curious occurrence in one of several cases which he had triturated simultaneously In one the lens opacities had completely clear [illegible] to this day The meth [illegible] advent of cocaine and [illegible]

Dr **FRANK A THOMAS** (Swansea) related the benefit derived in a case of dense nuclear opacity which disabled a workman for ten years, one month after he had matured the lens by trituration he extracted the lens and obtained [illegible] vision

Mr **MCHARDY** replied

Dr **KARL A GROSSMANN** (Liverpool) read a paper on

A Case of Astigmatism with Varying Axes.

The subject had eccentrically situated pupils, up and in After correcting his near vision under homatropine and ascertaining the most agreeable axes for the cylinders required—a downward and outward inclination from the vertical—he neutralised the mydriatic with eserine and found that for near vision axes having a rather more horizontal inclination were preferred. He thought the phenomenon was due to an eccentric and unequal suspension of the lens, such as was found in the extreme form in the case of aniridia he had demonstrated before the Association in 1902 and 1903. He had noticed other but less marked cases also associated with eccentric pupils.

Mr. **BERRY** said that cases in which there were slight differences in the axes of astigmatism for near and far vision were not uncommon; the differences depended upon the fact that corneal astigmatism differed over the corneal surface and that with pupils of differing sizes slightly different corneal areas were utilised, so that the summation of corneal and lenticular astigmatism varied.

Professor **G. J. BULL** (Paris) said that cases of eccentric pupils had been shown by Javal to be associated with incipient keratoconus and that with this association variability in the axes of astigmatism was exceedingly frequent.

Dr. **GROSSMANN** replied.

THURSDAY, JULY 28TH.

Dr. **HILL GRIFFITH** opened a discussion on

Intra-ocular Hæmorrhage and Systemic Disease.

At the outset he said he should exclude from consideration all those cases which arose from accident or from optic neuritis, from nephritis, retinitis, or disseminated choroiditis. He wished to consider intraocular hæmorrhages in eyes otherwise free from disease. Such primary or independent hæmorrhages might, like hæmorrhages elsewhere, occur from general conditions—blood changes, anæmia of pernicious types, purpura, scorbutus, and some forms of septic blood conditions, from diseased states of the finer vessels, from back pressure from the heart, and from embolic processes. The hæmorrhages were of most frequent occurrence in the retina, very rarely they might be choroidal, and perhaps, although he had seen none of the class, into the anterior chamber. In most cases of retinal hæmorrhages the retina itself was not changed in appearance apart from the effusion; in some cases there were also localised swelling and exudation probably secondary to the effusion. It had been customary to speak of the former as "retinal hæmorrhage" and of the latter as "hæmorrhagic retinitis" but it was doubtful if there was any real distinction other than that of degree. Intra-ocular hæmorrhages could not be very common, for among 6500 consecutive eye cases of all kinds seen in private there were only 33 cases of the condition, a proportion of 0·5 per cent. In hospital practice some 50 cases were recorded during the same period. These 83 cases might be classed thus: retinal hæmorrhage, 41; "hæmorrhagic retinitis," 20; "subhyaloid," 14; and into the vitreous, eight. In some cases the conditions overlapped. (A tabular list of the cases was shown.) The female sex showed a slightly greater liability than the male—47 as against 36; the preponderance was more marked in the subhyaloid variety—females ten and males four. In the subhyaloid variety the effusion was always about the macula. No difference could be ascertained in the liability of the two eyes. The prognosis both for sight and life was better for this form than for any other. Almost all the cases that were watched recovered with good vision and good health. Under the "vitreous" class were included only those in which there was evidence of a dark-red clot of some size. Many cases of dark floating opacities occurred which were probably of this nature, but for want of certain proof they were better excluded. In all these cases it was likely that the source of the effusion was the retina; in most cases this could be seen to be so. It was possible that the condition might arise from bleeding from the ciliary vessels but he had observed no case of the kind. Of the 61 cases forming the group of "retinal hæmorrhages" and "hæmorrhagic retinitis," a reasonable determining cause could be found for about half of the cases—straining in constipation, coughing in bronchitis or whooping-cough, gout, syphilis, purpura, Bright's disease, organic heart disease in conjunction with hemiplegia or hemianopsia, alcoholism, rheumatism, and the like. He was surprised how few cases were referable to coughing; the strain in "whooping" of children was very severe, as was not infrequently demonstrated by the marked conjunctival ecchymosis witnessed, but he found bleeding only rarely in the retina though he had made it a subject of systematic search. His observation of the association of sclerosis of retinal vessels with liability to small ruptures was in full accord with the extensive researches of Hirschberg, Steadman Bull, Marcus Gunn, and others; it was most marked. He, as well as others, had seen death from apoplexy follow the disregarding of warnings derived from the observation of the condition of the retinal vessels and the presence of minute hæmorrhages. In this connexion he would like to call attention to a point which he had noticed, that the cranial hæmorrhages, whether resulting in paresis or hemianopsia, tended to occur on the same side as the eye which had been noted earlier to contain effusions. Marked as was the liability to hæmorrhages in vessel degeneration it was small compared with the liability in blood changes. Some of the worst and most fatal cases which he had seen were in association with severe and malignant anæmia of varied origins. By way of making a comparative test of the frequency of the condition in hospital patients generally he had made a systematic examination of 500 medical patients whose pupils had been fully dilated. He had found 14 cases in the 500, or 2·8 per cent.—somewhat of a contrast to the 0·5 per cent. amongst his private eye patients.

Mr. **LUCIEN HOWE** (Buffalo, New York) said that he had witnessed hæmorrhages spring from the ciliary body; the effusion passed behind the lens, set up secondary glaucoma, and necessitated the removal of the eye. In general he was opposed to the assumption that all that appeared to be retinal were such; he was convinced that a great proportion should be properly described as choroidal.

Professor **UHTHOFF** showed specimens and drawings of two varieties of cases—an extreme præ-retinal, that which is commonly spoken of as subhyaloid but which he believed to be circumscribed by the retinal limiting membrane; and another of a case of a large post-retinal hæmorrhage which had dissected off the retina from the papilla to within a short distance of the ora serrata on one-half of the globe.

Dr. **RISLEY** (U.S.A.) emphasised the greater liability to hæmorrhages in blood changes over vascular degeneration. He illustrated the generalisation by reference to cases following malarial infection.

Professor **OLIVER** described three cases bearing on the same point. All were in negroes, and in all grave blood changes were demonstrated by blood counts and hæmoglobin estimations. The red corpuscles were reduced as low as 2,000,000, whilst the white were increased to over 200,000 per cubic millimetre, and the hæmoglobin fell to 25 per cent. The general disorders were diagnosed as splenic leucocythæmia and in one as pernicious anæmia. He described the fundus changes noticed and the conditions of the globes after death.

Dr. **G. CARPENTER** (London) was surprised to note the comparative infrequency with which hæmorrhages had been noted in the retina during whooping-cough. Some years ago he had made a systematic examination of a large number of children at the Evelina Hospital and had come to the conclusion that small effusions were by no means infrequent, both in the cough and in other conditions where the children struggled and cried with exceptional vigour. On the other hand, he had not found hæmorrhages in anæmia of children even when associated with enlarged spleens.

Some Practical Remarks on Magnet Operations.

Professor **J. HIRSCHBERG** (Berlin) said that during the last 25 years he had treated upwards of 300 cases of injury to the globe by steel particles by some application of the magnet, principally for the extraction of the intruding fragment. He had also carefully followed the published experiences of other workers and had noticed rules for the practice of the treatment which were somewhat of a puzzle to him. Foremost must always come the symptom of pain. Yet the absence of this indication must not be taken as indicating that no foreign body was present. In not a few such cases he had been able by the use of the sideroscope or by x-ray photography to demonstrate in the clearest manner a considerable fragment when no pain was complained of. He found the sideroscope to be a very suitable instrument provided it was so arranged as to be independent of general influences that so commonly existed in great cities owing to the extensive use of electric currents. He made it a point always to test the reliability of the instrument before and after use on the subject. It had been said that an encapsulated particle in a quiet eye, even though clearly demonstrated and localised, should be left alone. He thought the practice to be bad, as sooner or later the eye was sure to be a total loss. As regarded magnets, he used all [illegible] ciated use of ophthalmoscope and magnet, impossible in the larger forms. On the other hand, cures were effected by the giant form which were not possible with any weaker instrument. As yet the knowledge of the possibilities of the different instruments was not sufficiently distinct. But his inclination was to use the hand form in recent open wounds and to [illegible] giant; this it [illegible] after-regrets [illegible] was too early to come to a clear determination of the prospects attending these operations and to distinguish between the gravity of the varying positions *of the foreign body. In 64 cases 36, or 56 per* cent., retained good permanent vision; of these 23, or two-thirds of the whole, retained very good vision—i.e., from 1 to ½. In 22 cases excision followed the extraction. In conclusion, he lamented the recent decease of McKeown of Belfast to whose work so much of our present success with the magnet was due.

Dr. A. **BARKAN** (San Francisco) remarked on those cases in which a flying fragment of steel traversed the globe from end to end and became imbedded in the retro-orbital tissues. In such cases the careful application of x-ray methods would save a comparatively safe eyeball from further injury. In an experience of 70 cases he was able to corroborate the advantages derivable from the use of the sideroscope, especially the improved form of Hirschberg.

Mr. **MCHARDY** believed that the first step in the proper treatment of these cases was the stereoscopic localisation of the foreign body by x-ray photography and the sideroscope. Only by this proper [illegible] the danger be avoided [illegible] hand magnet in cases [illegible] fragment which had [illegible]

On the Visual Acuity of Savages.

Dr. W. H. R. **RIVERS** (Cambridge) said there was a strong popular idea that the eyesight of savage races was peculiarly keen and penetrating. Wonderful stories had been told of their extraordinary powers. He and others had conducted a very large series of experiments with the purpose of ascertaining the visual acuity of different peoples under similar conditions and tests. The best test was that of the letter E held in varying positions and at different distances. In all cases the examination was made with both eyes and in the open air. Races so diverse as the inhabitants of *Torres Straits, Borneo, Indian aborigines and Brahmins,* Mongols, negroes, and Europeans—civil, military, naval, and children at school—had been tested. It was found that there was very little difference over this wide range. There was a general average of acuity so that the letter E (of the size marked D = 6 of the Snellen test type) could be distinguished in any of its four positions at a distance of 13 metres. 50 per cent. of the subjects examined had two or three times "normal" ($\frac{6}{6}$) vision by this test. When abnormal cases of errors of refraction, which occurred in all races, were excluded the difference between races, savage or civilised, was extremely small. To what then was due the supposed great sight of savages? To a familiarity with their surroundings more than to anything else. The Australian tracker was a marvel in his natural habitat but no better than any country yokel when transported to Melanesia. In short, it was the development of their powers of [illegible] The visual acuity at [illegible] some investigation. I[illegible] 20 to 25 years was reached, then followed a period of constancy until 35 to 45 years when there was a decline. The decline was more rapid and earlier in onset in tropical countries than in home countries; this he thought was due to the earlier onset of lenticular changes which appeared much more frequently in hot climates. Our standard of "normal" vision ($\frac{6}{6}$) was a purely arbitrary one, for many psychological factors came into play in the reading of letters; these were not wholly excluded by the use of such a simple test as the E, for it was found that intelligent people could accurately judge the position of the letter even when its details were wholly blurred, by noting the slight deficiency of density on the open side of the letter.

Remarks on the Diagnosis and Treatment of Glaucoma.

Mr. **BERRY** said that despite the large amount of work which had been done with so much care by so many workers the real nature of glaucoma was still obscure. It was pretty certain that the altered balance in income and outgoing of the circulatory fluids of the eye was a factor and probably more a deficient outgoing than an increase in influx. Then there had been firmly established the part played by the changes in the anterior filtration angle; but with all this it was still impossible to explain the curative action exercised by the operatio[illegible] was a matter of difficulty [illegible] cases of slow progression [illegible] some had thought the distinction extremely difficult, but it had not seemed so to him, since he had been able to use the delicate test for the field of vision permitted by Bjerrum's *screen test which was greatly superior to that of the* ordinary perimeter and could be relied upon in cases where there was no increase in tension discernible. Von Graefe's original directions for iridectomy were most explicit. He insisted on a wide incision, as wide an iridectomy as possible, the tearing away of the iris as close to the ciliary processes as possible, and a slow evacuation of the aqueous. This procedure was based on the mistaken idea that the iris was a secreting surface. Mr. Berry's experience was distinctly in favour of iridectomy. He had little faith in the safety of myotics but his support of the operation was qualified by the method adopted. He preferred a keratome to the narrow-bladed knife; he did not seek to get his incision into the filtration angle. He doubted the possibility of doing this, but supposing it could be done, asked: What advantage would accrue to filtration by creating a cicatrix within the seat of the process? He found no necessity for the old iridectomy of extreme width and followed his narrower incision [illegible] Tyrrell's hook and the removal [illegible] segment of iris. In glaucoma [illegible] the disease but did not result in an improvement of the lost peripheral and central vision such as was a frequent result of operation in the acute *congestive cases.*

Mr. [illegible] experience of the [illegible] invaluable. To him [illegible] between certain low grades of glaucoma simplex and optic atrophy. The difficulty could be often cleared up by the instillation of cocaine. Should it be followed by the appearance of pulsating arteries in the fundus an increase of tension was indicated; also perimetry showed that the tendency to constriction of the field was early marked in atrophy and not in glaucoma. There could be no doubt as to the utility of iridectomy but it was not without danger in old folk in whom the zonula was weakened. In the glaucoma occasionally seen in myopes due, he thought, to a change in the filtration properties of the secreted fluids, the operation of sclerotomy was most successful.

Dr. W. A. **BRAILEY** (London) emphasised the necessity of early diagnosis and interference to obtain the best results, whether myotics or operation was relied upon. He was inclined to give more credit to the use of myotics than he had used to do but it must be begun early and continued without intermission. In cases where drugs appeared of no avail he did not hesitate to operate even though the visual acuity was high [illegible]

Mr. C[illegible] use of a [illegible] incision [illegible] the iris to its root, a point so strongly insisted upon by von Graefe, the introducer of the operation.

Professor **HIRSCHBERG** remarked that it was a life work to obtain a correct view of iridectomy in relation to glaucoma. He had recently published the results of his treatment of 600 cases. He found that the operation was best for the greatest number of patients. In some few cases it resulted in harm to the patient, for in some a malignant glaucoma supervened upon an iridectomy for glaucoma simplex. These disastrous results depended not on the operation but on the peculiar idiosyncrasy of the patient; in the greater number these patients were women. In other cases neither good nor harm resulted from operation; vision gradually diminished. He did not find myotics liable to produce conjunctival irritation as had been suggested; he was careful to see to the frequent sterilisation of fluids used.

Professor **UHTHOFF** summed up his experience of operation in this condition in a simple set of statistics: In 8 per cent. vision was a very little better for the operation;

in 40 per cent. the vision remained unchanged; in 40 per cent. there was no success, vision slowly deteriorated; and in 8 per cent. the patient was rendered the worse.

Mr. BERRY, in reply, said that in his experience the danger of malignant glaucoma referred to by Professor Hirschberg was extremely small; so rare was the condition that it should not deter from operation.

Mr. W. ADAMS FROST (London) read a paper on

Operative Treatment of Myopia.

The removal of the lenses for high myopia was an established surgical procedure. Better vision could be obtained and that without the use of glasses. He did not consider that success had been obtained unless these two results followed extraction. There were not many cases suitable for this form of treatment in England. In selecting cases they had to consider—1. The degree of myopia, which should not be less than 13 D., or one requiring the use of a correcting lens of 15 D. at 10 millimetres from the eye. 2. Visual acuity, and for this as good a test as any was the ability to read at the patient's remote point J. 1. The test was crude, yet it indicated a reasonable integrity of the retinal elements at the macula. 3. The age and general condition of the patient. The operative results were often marvellous; the question at issue was the permanence of the result: Did the procedure increase the liability of these folk to detached retina? They had to remember that patients were in any case liable to this disaster, a liability not known by any trustworthy statistics; that it was usual to operate on the worst eye, just the one most liable to detachment; then they had to estimate the nice point as to how long after operation a detachment occurring was due to the operation. He had seen detachment occur as early as ten weeks and as late as six years after operation. Then, again, they wished to know how long a period must lapse before they could consider the results obtained permanent. One of his cases had remained good for eight and a half years, 12 for five years, and four for three years. His impression was that the operation did enhance the danger of these eyes to detachment, but it was evident that it did not follow in the majority of cases. There was also the question whether after successful operation on one eye the second should be attempted. His opinion was unhesitatingly no; for it was almost impossible, in the unequal myopia of most of these eyes, to obtain equality of vision with the two eyes and, further, the patient lost the ability to read without glasses which the one myopic eye gave him.

Professor LANDOLT (Paris) said that he was aware of much in favour of the operation and he greatly disliked to disparage that which others praised. Yet he could not forget that myopia was only a symptom of a disease associated with grave changes in the uvea. These features tended to enhance the risks of extraction of mature cataractous lenses; how much more serious then in the removal of healthy lenses. In most cases of high myopia one eye was bad and the other was worse: were they to operate on the better eye in the hopes of a better result or to add to the hazards of the operation by choosing the worse eye? He thought that those cases only were suitable where the eyes were of nearly equal degrees of myopia and showed no gross fundus changes.

Mr. S. JOHNSON TAYLOR (Norwich) advocated repeated needling of the lens as less liable to produce alterations of tension than the rapid needling and evacuation of the lens matter.

Mr. FROST considered that the actual details of the operation could not affect the liability to detachment years after operation. He had utilised both the slow and the rapid methods but could find no indication that they influenced the ultimate issue.

Mr. ERNEST CLARKE (London) gave

A Résumé of 20 Years' Treatment of Myopia.

His habit, briefly stated, was to estimate the refraction of patients under 20 years of age with atropine, above that age with homatropine, fully to correct the error found, but not to give cylinders under 1 D. unless they were found to improve vision. He did not allow any reduction for near work. Of 1129 cases, 532 had been under observation for periods averaging four and a half years. Of these 460, with myopia varying from 0·75 D. to 20 D., remained stationary; in 152 cases the visual acuity had improved and in 63 cases the myopia had increased. Of these 63 cases, in 43 the increase was one dioptre or less, in 13 it was from 1 to 2 D., and in three it amounted to 4 D. Practically only 16 cases showed any noticeable increase in the myopia and in these the increase was not serious. He thought that these results tended to confirm the practice of giving full correction; it prevented that excessive convergence which was, he believed, the main factor in maintaining a progress of the disease.

Dr. A. MCGILLIVRAY (Dundee) communicated some observations on

The Temperature of the Cornea and its Relation to Corneal Therapeutics.

He had conducted several experiments on the temperature of the cornea and conjunctiva with the thermo-electric cup which agreed with the published work of Silex. The temperature of the healthy cornea was 10° less than that of the body, it was raised when the lids were closed, and when the eye was covered by pad and bandage it was nearly the same as that of the body. In inflammatory conditions a similar increase was found. These conditions had a marked influence on the growth of micro-organisms. Most of those likely to infect the eye flourished at an optimum temperature, practically that of the body. Hence it followed that covering the eye in inflammatory conditions tended to facilitate the growth of these organisms and also hindered the usual circulatory processes by rendering the eye immobile. He advocated an open treatment of inflammatory affections and the local use of cocaine as tending to reduce vascularity. The danger of desiccation of the corneal epithelium by the use of cocaine did not apply when ointments were used and large loose shades diminished the irritation of light.

THE ANNUAL EXHIBITION.

III.—SANITARY APPLIANCES, DISINFECTANTS, ETC.

The number of disinfectant preparations shown at the Oxford exhibition was decidedly smaller than in previous years though the representation of sanitary appliances in general was well maintained. Messrs. Doulton and Co., the well-known potters of Lambeth, had an interesting exhibit comprising white glazed fire-clay sinks, a white vitreous enamelled rolled-edge bath, and the "Compact" Simplicitas wash-down closet. The strong white earthenware circular-fronted lavatory should also be mentioned. It is fitted with a vulcanite removeable "waste" fixed in the recess, a patent combined hot and cold supply fitting being fixed in the wall and actuated by the foot the temperature of the water being controlled by the left or right movement of a pedal. The Jeyes' Sanitary Compounds Company, Limited, of 64, Cannon-street, London, E.C., exhibited specimens of "cyllin"—formerly sold as creolin and now described as a new coal-tar disinfectant free from carbolic acid or its homologues and containing a new substance discovered in tar. There were preparations for special medical use and for domestic purposes. Bacteriological experiments show that "cyllin" is 11 times more efficient as a germicide than is pure carbolic acid on the bacillus typhosus and 30 times more efficient when tested against the bacillus pestis, while its toxic properties are eight times and its caustic properties ten times less than that of tar acid. An emulsion of "cyllin"—1 in 800 strength—is sufficient, it is stated, to sterilise sputa infected with tubercle bacilli. It has been used in the form of spray in inhalation with some success in tubercle of the lungs. The Berkefeld Filter Company, Limited, of 121, Oxford-street, London, W., exhibited many adaptations of the Berkefeld filter. This filter is known as an effective remover of germs from drinking water and its action is relatively rapid. The Peat Products Company of 71A, Great *Russell-street, London*, W.C., exhibited their interesting "sphagnol" preparations, sphagnol being described as a combination of the antiseptic and emollient vegetable tars and oils obtained in the distillation of peat. It is suitably incorporated with soap. Lints, cotton-wools, absorbent gauze tissue, bandages, surgeons' tow, splint padding, and sheet wadding were the specialties exhibited by the Liverpool Lint Company of Mark-street Mills, Netherfield-road North, Liverpool. A very interesting product is petol (Petol, Limited of 86, Cannon-street, London, E.C.), a base derived from peat and possessing marked antiseptic properties. It has been used in eczema and ringworm with distinct advantage. Petol may be obtained in several forms, amongst which are a salve, suppositories, soaps, and a disinfecting fluid and powder. Mention might appropriately be made in this section of the sanitary mattress of the Marshall

Sanitary Mattress Company, Limited, of 34, Eagle-street, London, W.C. The mattress seems to us fully to justify the adjective "sanitary." It contains over 1000 coppered steel springs, each of which is encased in an upright position *in a separate calico pocket and works independently of* the others. There are thus no friction and no noise and it is difficult to see how such an arrangement could get out of order. Moreover, protected ventilators are placed at each end which allow a free circulation of air which is naturally changed by every movement of the occupant. The same *principle is applied to a pillow, a mattress support,* and a folding bed.

IV.—FOODS AND FOOD PRODUCTS.

Milk and milk products formed a large proportion of the exhibits in this section. Amongst the best known dry-milk preparations is plasmon the nutrient value of which has been thoroughly established in both clinical and dietetic practice. The preparations shown by the International Plasmon, Limited, of 66A, Farringdon-street, London, E.C., and 56, Duke-street, Grosvenor-square, London, W., included plasmon biscuits, diabetic biscuits, plasmon cocoa, beef plasmon, and plasmon arrowroot, the latter being found excellent as a real food in diarrhœa and dysentery without any irritating action upon the bowel. The Aylesbury Company, Limited, of St. Petersburg-place, Bayswater, London, W., showed an excellent series of specially prepared milks—humanised milk, sterilised milk, peptonised milk, cream milk, koumiss, and so forth. The milk employed is obtained from farms periodically inspected by medical and veterinary officers. The "klonol" brand of dried milk shown by Messrs. Irven and Co., of 7 and 8, Union-court, Old Broad-street, London, E.C., represents the entire solid constituents, including the fat, of milk. It is therefore a complete food, but it would be important to determine how far the nutrients are chemically and physiologically modified by the process of manufacture which consists in evaporating the milk rapidly at a high temperature. A similar preparation was that shown by the Galak Milk Products, Limited, of 118, Fenchurch-street, London, E.C., under the name of "galak." In this case, it is asserted that *dietetically* there is no difference between the food value of this dried preparation and fresh milk. Messrs. Fairchild Brothers and Foster of Snow-hill-buildings, London, E.C., presented an instructive exhibit illustrating the preparation of "panopepton" which is made [illegible] in the convalescing stage and answers admirably as a nutrient in disordered nutrition. The exhibit included "peptogenic milk powder," by the use of which milk exhibiting the composition of huma[illegible] from cow's milk; pepsencia, [illegible]ciples of the peptic glands; a[illegible]psin, trypsin, and diastase. Meat preparations in very great variety were shown by several well-known firms. Bovril, Limited, of 152 to 166, Old-street, City-road, London, E.C., showed in association with bovril preparations the excellent food virol, an emulsion of red bone marrow, malt extract, and eggs, forming an efficacious and agreeable substitute for cod-liver oil. Messrs. Armour and Co., Limited, of 46A, Holborn Viaduct, London, E.C., showed digestive ferments, beef-juice, extract of red bone marrow, and various preparations of the powerful hæmostatic principle of adrenal substance, and various glandular extracts in powder *and tablet form.* Liebig's Extract of Meat Company, Limited, of 4, Lloyd's-avenue, London, E.C., exhibited lemco, a highly concentrated beef extract free from fat; and oxo, a fluid beef containing the nourishing as well as the stimulating crystalline substances of beef. Messrs. Brand and Co., Limited, of 11, Little Stanhope-street, Mayfair, London, W., showed specialities for invalids, essences of beef, mutton, veal and chicken, turtle jelly, and soup, meat juices and a nutrient beef powder; and the Peptenzyme Company, of 80, Gloucester-road, South Kensington, London, S.W., exhibited peptenzyme, containing the digestive secretions of the salivary, peptic, pancreatic, hepatic, and splenic glands; protonuclein, said to contain the tissue-building agencies of the lymphoid glands; and trophonine, an agreeable and readily assimilable *liquid food.* Of foods prepared for special purposes may be mentioned those made by Messrs. G. Van Abbott and Sons of Baden-place, Crosby-row, Borough, London, S.E., for sufferers from diabetes, dyspepsia, and obesity, including starchless bread and biscuits, almond bread, and bran gluten. Messrs. Callard and Co. showed an assortment of new foods specially adapted for diabetic patients—e.g., sugarless marmalade, chocolate, beverages, jellies, and starchless breads, biscuits, and cakes. The list may be closed by referring to the preparation known as ovo-lecithin, a pure distearo-glycerophosphate of choline made entirely from the yelk of egg (Billon's Ovo Lecithin Depôt, 16, Water-lane, Great Tower-street, London, E.C.). Ovo-lecithin acts favourably on the processes of *nutrition and hence has proved valuable in chlorosis,* anæmia, and nervous disorders.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary Comitia was held on July 28th, the PRESIDENT, Sir WILLIAM SELBY CHURCH, Bart., K.C.B., being in the chair.

The following gentlemen having passed the requisite examination were admitted as Members of the College: John Frederick Gordon Dill, M.A., M.D. Cantab.; Edward Henry Douty, M.A., M D. Cantab., L.R.C.P. Lond.; Wilfred Stephen Fox, M.A. Cantab., L.R.C.P. Lond.; Ernest Edward Glynn, M.A., M.B. Cantab., L.R.C.P. Lond.; Henry Lawrence McKisack, M.D. R.U.I.; Geoffrey Richard Slade, M.A., M.D. Cantab., L.R.C.P. Lond.; and Thomas Grainger Stewart, M.B. Edin.

Licences to practise physic were granted to 115 gentlemen who had passed the required examination.

Diplomas in Public Health were granted to the following gentlemen: Charles Thomas Blackwell (Major R.A.M.C.), M.D. Durh., L.R C.P. & S. Edin.; Dunstan Brewer, L.R.C.P. Lond., M.R.C.S. Eng.; John Catto, M.B., B.S. Aberd.; Basanta Kumar Chatterjee, L.R.C.P. & S. Edin., L.F.P.S. Glasg.; Stanley Cornell Clapham, L.R.C.P. Lond., M.R.C.S. Eng., M.B., B.S. Durh.; John Matthewson Clements, M.B., B.Ch. R.U.I.; Walter Ernest Llewellyn Davies, L.R.C.P. Lond., M.R.C.S. Eng.; Thomas Stokoe Elliot, L.S.A.; Norman Faichnie (Major R.A.M.C.), M.B., B.S. Durh.; Henry William Grattan (Captain R.A.M.C.), L.R.C.P. Lond., M.R.C.S. Eng.; John William Gromitt, L.R.C.P. Lond., M.R.C.S. Eng.; Hugh Llewelyn Jenkins, M.B., Ch.B. Vict.; John Isaac Pratt, L.R.C.P. Lond., M.R.C.S. Eng., M.B. Toronto; Morgan James Rees, L.R.C.P. Lond., M.R.C.S. Eng., M.B. Lond.; Frank Ernest Rock, L.R.C.P. Lond., M.R.C.S. Eng., M.D. Lond.; Godfrey William Simpson, L.R.C.P. Lond., M.R.C.S. Eng.; Charles Augustus Spooner, L.R.C.P. & S. Edin., L.F.P.S. Glasg.; John Charles Baron Statham (Captain R.A.M.C.), L.R.C.P. Lond., M.R.C.S. Eng.; John Robert Steinhaeuser, L.R.C.P. Lond., M.R.C.S. Eng., M.B. & B.S. Lond.; Robert Lewis Thornley, L.R.C.P. Lond., M.R.C.S. Eng., M.D. Lond.; Philip Vickers, M.B., Ch.B. Edin.; and William McConnel Wanklyn, L.R.C.P. Lond., M.R.C.S. Eng.

The following communications were received:—

1. From the secretary of the Royal College of Surgeons of England reporting certain *proceedings of its Council* on July 14th.

2. From the Lord President of the Privy Council in reply to the College respecting the Parliamentary Bill proposed by the General Medical Council.

3. From Mr. Edmund Gosse, librarian to the House of [illegible] (*a*) the portrait of [illegible]ne in possession of [illegible]l.

4. From Dr. Tyson asking leave to have photographs taken of the portraits of Dr. Edward and Dr. Richard Tyson in the College.—The application was *granted.*

5. From the Board of Education asking the advice of the College as to the formation of a consultative committee to control the general system of school certificates for elementary schools.—The matter was referred to the committee of management.

On the nomination of the President and Council the following appointments were made: Censors: Dr. Thomas Henry Green, Dr. William *Henry Allchin,* Dr. *Norman Moore,* and Dr. *Frederick Taylor. Treasurer:* Sir Dyce Duckworth. Emeritus Registrar: Sir Henry Alfred Pitman. Registrar: Dr. Edward Liveing. Harveian librarian: Dr. Joseph Frank Payne. Assistant registrar: Dr. Oswald Auchinleck Browne.

Elected members of the library committee: Dr. Philip Frank, Dr. Norman Moore, Dr. William Henry Allchin, and Dr. Archibald Edward Garrod. Curators of the museum: Dr. William Howship Dickinson, Dr. Henry Charlton Bastian, Dr. William Cayley, and Dr. John Abercrombie. Finance committee: Dr. George Fielding Blandford, Dr. James Frederick Goodhart, and Sir Isambard Owen. Examiners: Chemistry and chemical physics: Mr. Harold B. Dixon, F.R.S., Mr. John Millar Thomson, F.R.S., Mr. Frederick Daniel Chattaway, Ph.D., D.Sc., Mr. Alexander Mitchell Kellas, F.C.S., and Mr. John Addyman Gardner, F.C.S., F.I.C. Materia medica and pharmacy: Dr. Frederick Willcocks, Dr. Walter Essex Wynter, Dr. Henry Albert Caley, Dr. Francis Whittaker Tunnicliffe, and Dr. James Purves Stewart. Physiology: Dr. Ernest Henry Starling, Dr. Bertram Louis Abrahams, and Dr. Leonard Erskine Hill. Anatomy: Dr. Bertram C. A. Windle, F.R.S., and Dr. Robert Howden. Medical anatomy and principles and practice of medicine: Dr. Samuel Hatch West, Dr. Theodore Dyke Acland, Dr. George Newton Pitt, Dr. Sidney Philip Phillips, Dr. William Pasteur, Dr. William Collier, Dr. Norman Dalton, Dr. Frederick John Smith, Dr. Francis George Penrose, and Dr. John Rose Bradford, F.R.S. Midwifery and diseases peculiar to women: Dr. Alfred Lewis Galabin, Dr. Francis Henry Champneys, Dr. George Ernest Herman, Dr. William Rivers Pollock, and Dr. Edward Malins. Public health: Part I.—Dr. Arthur Pearson Luff. Part II.—Dr. William Heaton Hamer.

The PRESIDENT announced that he had nominated Dr. Frederick Roberts as Harveian orator for 1905. He also gave notice that Dr. F. F. Caiger would deliver the Bradshaw lecture on Nov. 15th instead of on Nov. 3rd as previously announced.

Sir WILLIAM BROADBENT was re-elected a representative on the executive committee of the Imperial Cancer Research Fund.

A report dated July 18th was received from the committee of management. The committee recommended that Felsted School, Felsted, which is already recognised for instruction in chemistry, physics, and practical chemistry, should be now recognised for the teaching of biology. Also, that St. Mary's Hospital, Manchester, should be recognised as a place of instruction in midwifery and gynæcology. The committee reported that it had considered the communication from the General Medical Council containing various resolutions in regard to the teaching and examination of the subjects of the first year of the curriculum and that such resolutions of the General Medical Council do not recommend anything which is not already included in the latest regulations of the Conjoint Board.—The report was adopted.

The quarterly reports of the College Finance Committee, of the Library Committee, and of the curators of the museum were received and adopted. After further routine business had been conducted the PRESIDENT dissolved the Comitia.

THE CONGRESS OF THE SANITARY INSTITUTE.

THE twenty-second Congress of the Sanitary Institute was held at Glasgow from July 25th to 30th under the Presidency of the Right Hon. Lord BLYTHSWOOD, LL.D. The proceedings began on the 25th, with a reception of the members of the Congress in St. Andrew's Hall by the Lord Provost, followed by an inaugural address by the President, Sir RICHARD DOUGLAS POWELL, who took for his subject the Prevention of Consumption. He urged the importance of physical training in schools and dwelt on the necessity for adequate ventilation and cleanliness in dwellings. It was from the poor and crowded populations that the vast death-rate from consumption arose. It was from them that the great bulk of poisoned material emanated; yet measures for the treatment of consumption amongst the poor were as yet hopelessly inadequate. If the death-rate from consumption was to be decreased the municipal authorities throughout the kingdom would have to make great improvements upon the work which had already been done.

On the following day the sectional meetings of the Congress were opened at the University, the University court having granted facilities for this purpose. There was a large attendance of members including delegates from medical and municipal authorities in all parts of the country and many sanitary authorities from the continent.

SANITARY SCIENCE AND PREVENTIVE MEDICINE.

The section of Sanitary Science and Preventive Medicine met under the presidency of Professor J. GLAISTER (Glasgow), who in his opening address dealt with the influence of small-pox hospitals upon neighbouring populations with regard to the spread of the disease. In this connexion he discussed the doctrine of aerial dissemination and contrasted the position of this country with that of Germany with respect to the treatment of small-pox in hospitals. He thought that much of the evidence in support of aerial dissemination was of a very flimsy character. The history of the Glasgow epidemic abundantly showed that the practice of vaccination by giving an immunity against small-pox for a given number of years had caused, when small-pox made its appearance in the city, the development of a large number of mild ambulant cases of the disease which were not discovered and which did not call for medical attendance. That such cases were numerous in Glasgow the evidence of the medical officer of health was clear. Hence, if in the future they expected to deprive small-pox of its great anxiety to communities, then revaccination as practised in Germany must become the law; and before they could determine that aerial dissemination played any part in the propagation of the disease certain critical tests must be employed statistically and otherwise in any epidemic, so that the direct and mediate sources of infection are exhausted before this theory is invoked to account for the circumstances. In Germany the practice of vaccination and revaccination, he said, was universal and if revaccination became compulsory in this country after a comparatively few years it would be possible for small-pox hospitals as such to fall comparatively into disuse.

In the same section Dr. EBENEZER DUNCAN (Glasgow) raised a discussion on the following motion:

> In view of the prevalence of phthisis pulmonalis in the working-class population of Great Britain and of the suffering, pauperism, and death resulting from the dissemination of that disease this Congress recommend the council of the Sanitary Institute to memorialise the Local Government Boards of England and Scotland to allow health authorities to add phthisis pulmonalis to the schedule of notifiable diseases.

Dr. Duncan afterwards agreed to the deletion of the reference to the working classes and to the motion being altered so that the memorial should be to the effect that local authorities should be allowed to make the disease notifiable on such conditions as might be approved by the Local Government Board. In this form the motion was passed by a very large majority.

The other subjects discussed in this section were: The Cause of Small-pox, Inspection of School Children, Malaria and Consumption in the Tropics, Infantile Mortality, and the Sanitary Condition of Vessels.

In dealing with the latter subject Dr. WILLIAM WRIGHT, medical officer to the Glasgow port local authority, advocated that port local authorities should combine in one strenuous effort to take over into their own hands the sanitary supervision of ships and to displace the Board of Trade from a position which up to the present had been nothing short of a sinecure. The officers of the Board of Trade, he contended, had no real knowledge of the sanitary requirements of a ship. The power should therefore be transferred to those who were properly qualified to advise. After further discussion the following motion was adopted:—

> In consideration of the sanitary condition of the mercantile marine this section is of opinion that the sanitary control of ships both during and after construction should be vested in port sanitary authorities and that medical inspectorships for shipping should be created in the staffs of the Local Government Boards of England, Ireland, and Scotland to supervise all suggestions from such port authorities for the consideration and approval of the Board; and the section recommend the council of the Institute to bring the proposition under the notice of the proper authorities.

The work of the other sections, which was of a more technical character, can only be referred to very briefly. The section devoted to Engineering and Architecture met under the presidency of Professor H. ROBINSON. Among the papers read and discussed were those dealing with the Supervisory Control of Water Supplies, Domestic Sanitary Engineering, House Drainage, and Uniform Distribution of Sewage on Filters.

The section devoted to Physics, Chemistry, and Biology also met, Professor FRANK CLOWES (London) presiding. In

his address he referred to two subjects which were of
as a city—namely the best
urity of the atmosphere and of

ago

MUNICIPAL AND OTHER CONFERENCES

A series of conferences of special bodies—municipal representatives, engineers and surveyors to county and other sanitary authorities sanitary inspectors and medical officers of health also took place and an important conference was held on the Hygiene of School Life

At this latter conference Dr A K CHALMERS medical officer of health of Glasgow read a paper with reference to the Examination of School Children in Glasgow His results more or less confirmed the impressions which the anthropometric committee years ago made plain—viz that in towns there were children of corresponding ages who were both smaller in stature and less in weight than children brought up in the country Grading children according to the class of house in which they lived it was found that those who lived in houses of three rooms and upwards had a better physique judging by height and weight, than those living in houses of two rooms, and again that the latter were better developed than those living in houses of one apartment These facts had an important bearing on the measures to be adopted for the physical training of children and established a case for further inquiry both as to food and clothing

At the conference of sanitary inspectors Mr PETER FYFE (Glasgow) read a paper entitled What People Sleep on an outcome of an investigation into the bed making trade As a result of his examination as to the nature of wool flock he found that it was manufactured from a mass of rags the rejected of every class of the population Nothing in the nature of cleansing or disinfection was attempted All went into the machine if sufficiently dry and became transformed into flock The very filthy character of this material was proved by both chemical and bacteriological examination The results obtained in the words of Dr R M Buchanan city bacteriologist indicated an amount of uncleanliness in the form of live potential dirt that was shocking to contemplate when the purpose for which the material was used was considered and revealed a state of matters calling for remedial action At the present time, however sanitary officials were powerless to cope with this widespread evil—one well calculated to bring disease into the closest proximity with the labouring class

At the conference of medical officers of health the subjects dealt with were chiefly those relating to the notification of tuberculosis and the control of small pox contacts After the discussion on the latter subject the following motion was passed —

> That this Congress is
> seriously through the t
> mend the council of th
> take such measures as
> risk of disseminating infection

A conference of women on Hygiene under the presidency of the Duchess of MONTROSE was also held at which such subjects as the physical training of women and the registration of nurses were discussed

The entertainment of the members and their friends received the necessary attention and general satisfaction was expressed at the great success which had attended the whole proceedings of the Congress

ROYAL COLLEGE OF SURGEONS OF ENGLAND

AN ordinary meeting of the Council was held *on July 28th*, the President Mr JOHN TWEEDY being in the chair

The SECRETARY reported the death at the age of 87 years of Sir John Simon K C B past President of the College

The following motion was passed

> The Council
> Simon K C B

Diplomas of Membership were directed to be issued to 115 candidates and in conjunction with the Royal College of Physicians of London diplomas in public health were directed to be issued to 22 successful candidates

The report of the Finance Committee was received and adopted The main items of the report were as follows The gross income of the College for the past year amounted to £26 969, being £547 more than last year From the examinations of the Conjoint Examining Board for England there was a decrease of £315 The incidental
ining Board were £558 more
were chiefly due to letting
om candidates for the Fellowship there was an increase of £165 From the Licence in Dental Surgery there was a decrease of £51 The expenditure amounted to £24 174 or £242 less than in the previous year The expenses of the examination hall were £204 less than last year The museum cost £204 less than last year The extraordinary expenditure was heavy, amounting to £1014, the chief item of which was a premium of £418 for a seven years policy of fire insurance The balance of income over expenditure amounted to £2794 During the year the investments of the College have been increased by £1000 Local Loans 3 per cent stock and £1500 London County 3 per cent stock A sum of £1612 has been expended upon the *redemption of the land tax on* portions of the College property

On the recommendation of the committee of management it was resolved that Felsted School should be recognised as a place for instruction in biology and that St Mary s Hospital, Manchester should be recognised as a place of instruction in midwifery and gynæcology

The following report from the delegates appointed to consider the letter from the Colonial Secretary in reference to diplomas in tropical medicine was received and adopted —

> Royal Colleges that, having
> ary of State for the Colonies

Mr R J Godlee was appointed as visitor and the President was authorised to appoint an additional representative if he should think it desirable

A letter was read from Mr Robert L Morant, secretary to the Board of Education forwarding a copy of certain suggestions submitted to the Board by the consultative committee for a system of school certificates stating that the Board is anxious to obtain an expression of the views of the Universities and other bodies interested upon the important issues raised in the suggestions, and requesting that the Board may be favoured not later than Dec 31st 1904 with the outcome of such consideration as may be accorded to the scheme

The letter was referred to a committee to consider and report

MEDICINE AND THE LAW

Byrne v Thorne

THE action brought by a patient against Miss May Thorne for alleged negligence whereby a mattress sponge was left in the plaintiff s abdomen at the conclusion of an operation performed by the defendant was brought to a conclusion now some weeks ago and resulted in a verdict for the plaintiff for £25 damages All our readers know the circumstances of the case and know also that Miss Thorne received from the medical profession a practical testimony of sympathy in the payment of her damages and costs But there are aspects of the case which may be further alluded to

The directions of the learned judge to the jury the questions left to the latter by him the damages which were awarded, and the manner in which the finding was deliv are features in the case which are of general interest from a medico-legal point of view, as the danger of such an occurrence taking place is one to which all surgeons are liable. With regard to this danger a letter from Mr. A. M. Sheild in THE LANCET of June 11th, p. 1684, suggested that mechanical methods may assist the surgeon in ascertaining whether the nurse's or house surgeon's duties have been accurately performed. The suggestion is of importance having regard to the extended responsibility which the recent trial appears to throw upon the surgeon, but Mr. Sheild's views are not shared by many surgeons. All mechanical services are liable to break down, because, after all, they are served by human intelligence. Mr. Justice Bruce told the jury that the point which they had to consider was whether the defendant had been guilty of a want of reasonable care. Skill and care are different things and there was no suggestion of want of skill in this case. The jury had already heard from Mr. H. F. Dickens, K.C., the summary of the law of negligence as applied to medical matters by Chief Justice Erle in Rich *v.* Pierpont,[1] who in summing up the case before him said that the action charged the medical man "with a breach of his legal duty by reason of inattention and negligence and want of proper care and skill" and instructed the jury that if they were of opinion that there had been a "culpable want of attention and care" the medical man would be liable. It was in this judgment that it was laid down that a medical man was not answerable merely because some other practitioner might have shown greater skill and knowledge but that he was bound to have a "competent degree" of both, and that it was not enough in order to make the defendant liable to show that he might have used a greater degree of skill, or even that he might reasonably have employed a higher degree of care. "The question was whether there had been a want of reasonable care and skill to such an extent as to lead to the bad result." In other words, the law in such cases has always been understood to be that the medical man is expected to exercise a reasonable amount of skill and a reasonable amount of care, but that he is not to be held liable to his patient if he did not exercise both or either in the highest conceivable degree, the question what may constitute reasonable skill and reasonable care being for the jury.

In dealing with the facts in the case before him Mr. Justice Bruce dwelt upon the circumstance that although the mistake in counting the sponges was that of the nurse, the counting by the nurse had not been checked before and after the operation by the surgeon, and the absence of this possible precaution evidently weighed with his lordship. The questions left by him to the jury were as follows: (1) Was the defendant guilty of a want of due and reasonable care in regard to the counting or superintending the counting of the sponges? (2) Was the nurse employed by the defendant to assist during the operation? (3) Was the nurse guilty of negligence in counting the sponges? (4) Was the counting of the sponges a vital part of the operation the defendant undertook to perform or to see performed? (5) Was the nurse under the control of the defendant during the operation? With regard to the second and fifth questions it may be observed that they point to a possible liability of the surgeon for the acts of the nurse apart from the performance of his own duties, a liability which has not, so far as we are aware, ever been established. As, however, the first and fourth questions were answered in the affirmative, the second and fifth became superfluous. Mr. Justice Bruce undoubtedly thought that the surgeon ought to make sure for himself, wherever it was reasonably possible for him to do so, not by inquiry but as a matter of personal knowledge, that nothing was left in the patient's body that should be removed before closing the wound, and he guided the jury to an expression of this view in their verdict. The jury considered their verdict for two hours and on their return to court answered all the above questions in the affirmative, adding to their reply to the first a rider that in their opinion the operation was very skilfully performed. With regard to the damages they assessed them at one farthing, a sum which the judge pointed out was inconsistent with answers which attributed negligence to the defendant, and he accordingly declined to accept it from them. The verdict was no doubt, strictly speaking, illogical as if a defendant has caused injury to a plaintiff by negligence he must be answerable for the natural result of his negligence. Such a finding was not, however, unnatural, nor one altogether unusual where a jury of twelve men try a difficult and complicated issue upon which divergent views may reasonably be held. It was, no doubt, the result of a compromise between those who were of opinion that the defendant had not shown any want of reasonable care, such as to involve liability for negligence, and those who thought that more care should have been taken but who still did not think that the surgeon deserved to incur a heavy pecuniary loss. Evidently large damages were not considered necessary by any, for upon the judge refusing to accept the verdict of a farthing the jury reconsidered the matter and raised the amount to £25 only. This may be taken to show that they considered that the supervision of the counting by the surgeon was a practical precaution the absence of which was to be regretted, but that they did not hold it to be one so imperatively called for or so indicated by custom that its omission would justify the exaction of a heavy penalty. The verdict, in short, showed careful and sympathetic consideration of the case and intelligent appreciation of the difficulty of eliminating all error, combined with the hardship of imposing the responsibility even for an avoidable mistake upon the surgeon.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the General Sanitary Circumstances and Administration of the Romford Rural District and on Prevalence of Diphtheria in Certain Localities therein, by Dr. F. ST. GEORGE MIVART.[1]—We are as yet far from possessing any adequate explanation of the local incidence of diphtheria. In any given epidemic it is usually possible to trace opportunities of infection from person to person and sometimes these opportunities are found to have been so numerous that the whole outbreak appears easily to be accounted for. The difficulty, however, remains that the conditions of personal infection which usually seem to be associated with the spread of the disease are common to almost any locality. There is seldom anything in "school influence," unrecognised cases, infected slates, handkerchiefs, drinking cups, and the like which can be considered peculiar to particular neighbourhoods which are frequently and severely attacked by diphtheria; similar opportunities of infection abound in other districts which seem as often to escape epidemics when diphtheria is introduced. It is thus important that the essentially local conditions of diphtheria-infected districts should continue to be studied. The southern part of the Romford rural district, which includes the parishes of Dagenham and Rainham, in recent years has suffered from exceptional prevalence of this disease and in the latter parish, which contains 343 inhabited houses, nearly 200 cases of diphtheria were notified in the course of last year. Opportunities of personal infection were, as usual, numerous and Dr. Mivart deals with the operation of the elementary schools in this direction. He also gives an interesting account of the locality concerned. It forms part of the long stretch of flat country which borders the Thames on the Essex side. Fogs are frequent and the climate is cold, damp, and exposed to east winds. The country is intersected by ditches containing stagnant water and much contaminated by overflows from cesspools and by slop water from the houses. Neither Rainham nor Dagenham is at present sewered. Both have a public water-supply and probably this circumstance increases the nuisance which constantly arises from overflowing cesspools—an evil which the local authority seems to do little to remedy. The most objectionable nuisances in the district, however, are those caused by the great quantities of London manure which are taken by rail to Rainham and Dagenham for use on market gardens and also those due to a very offensive trade, the manufacture of "artificial guano" from fish offal. These conditions occasion an abundance of flies and the possible share of flies in carrying diphtheria through food and in other ways should not be lost sight of The relation of the manure and other nuisances to the prevalence of non diphtheritic sore throat is another matter to which Dr Mivart draws attention It should be observed that the case mortality during the epidemic in 1903 in Rainham was low—less than 3 per cent—and it would be interesting to know how far this may be attributed to the use of diphtheria antitoxin In reviewing the condition of the whole of the Romford rural district Dr Mivart *points to a number of objectionable* and dangerous sanitary conditions to which the responsible local authority should give immediate attention The need for supervision of the cowsheds in the place, which supply the London market, seems to be specially great and the contamination of milk in local dairies by means of flies is another important point on which stress is laid Many of the dwelling houses in Romford seem to be dilapidated and exceptionally damp

[1] London, Eyre and Spottiswoode, East Harding-street; Edinburgh, Oliver and Boyd; Dublin, E. Ponsonby. Price 4*d.*

On the General Sanitary Circumstances and Administration of the Whittlesey Urban and Rural Districts, by Dr S MONCKTON COPEMAN[2]—The village and urban district of Whittlesey, with a population of just below 4000, is situated on what was formerly an island in the fen country about six miles south east of Peterborough It is mainly a collection of small houses and many of the inhabitants are brickmakers Dr Copeman points out a large number of insanitary conditions several of which could be remedied without much expense by a satisfactory local authority The most pressing need of the village is a wholesome water supply and apparently this could be secured at a comparatively small cost either by extension of the Peterborough mains or from the Wisbech waterworks The district however, has a local Act by which no greater rate than 3*s* 6*d* in the pound can be raised in any one year without the sanction of a town's meeting and the inhabitants have hitherto invariably refused to sanction any additional rating for water or for other sanitary purposes It is to be hoped that this attitude will be changed now that Dr Copeman has shown the feasibility of a satisfactory scheme of water supply which is needed also for certain villages in the adjoining rural district

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 8748 births and 4793 deaths were registered during the week ending July 30th The annual rate of mortality in these towns, which had been 13 5, 13 7, and 14 1 per 1000 in the three preceding weeks further rose last week to 16 4 per 1000 In London the death rate was 16 0 per 1000, while it averaged 16 5 per 1000 in the 75 other large towns The lowest death-rates in these towns were 2 6 in Smethwick, 4 5 in Hornsey, 7 0 in King's Norton 7 4 in Northampton, 8 0 in Rotherham, and 8 7 in Croydon and in Handsworth, Staffs, while the highest rates were 22 1 in West Ham, 22 6 in Birmingham, 24 7 in Rhondda, 25 8 in Stockport 27·1 in St Helens, and 29 8 in Liverpool The 4793 deaths in these towns last week included 1255 which were referred to the principal infectious diseases, against 500 506 and 792 in the three preceding weeks, of these 1255 deaths, 947 resulted from diarrhœa, 156 from measles, 57 from whooping cough 35 from diphtheria, 33 from scarlet fever, 22 from "fever (principally enteric), and five from small pox No death from any of these diseases was registered last week in Hornsey, Hastings Bournemouth, King's Norton, Smethwick or West Hartlepool, while the highest death rates from the principal infectious diseases were recorded in West Ham, Leyton, Birmingham, Aston Manor, Nottingham Stockport, Liverpool, Bootle, and St Helens The greatest proportional mortality from measles occurred in Hanley, Grimsby, Birkenhead, St Helens Huddersfield, and Hull, from scarlet fever in Great Yarmouth and Barrow in Furness, from whooping cough in Burton on Trent and St Helens, from diphtheria in Reading, and from diarrhœa in Tottenham West Ham Leyton, Birmingham, Aston Manor, Nottingham, Stockport Liverpool and Bootle The mortality from "fever' showed no marked excess in any of the large towns *Of the five fatal cases of small pox* registered in these towns last week, two belonged to London and one each to Warrington, Manchester, and Newcastle-upon-Tyne The number of small-pox patients in the Metropolitan Asylums hospitals at the end of last week was 46, against 71, 62, and 51 at the end of the three preceding weeks, seven new cases were admitted during the week, against ten, seven, and six in the three preceding weeks The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 1685, 1698, and 1754 *on the three* preceding Saturdays, had increased to 1784 on Saturday last, July 30th, 243 new cases were admitted during the week, against 269, 229, and 234 in the three preceding weeks The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 135, 155, and 120 in the three preceding weeks, fell again [illegible] ght above the number in [illegible] r The causes of 50, or 1 [illegible] in the 76 towns *last week were not certified either by a registered medical* practitioner or by a coroner All the causes of death were duly certified in West Ham Bristol, Leicester, Nottingham, Salford, Leeds Newcastle upon Tyne, and in 45 other smaller towns, while the largest proportions of uncertified deaths were registered in Birmingham, Sheffield, Liverpool, Bootle, and Manchester

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in eight of the principal Scotch towns, which had been 15 8, 14 8 and 15 7 per 1000 in the three preceding weeks declined to 14 1 per 1000 during the week ending July 30th, and was 2 3 per 1000 below the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 9 0 in Greenock and 10 8 in Aberdeen to 16 6 in Dundee and 19 9 in Paisley The 466 deaths in these towns included 24 from diarrhœa, 19 from whooping cough, seven from measles four from "fever" two from scarlet fever, and two from diphtheria In all, 58 deaths resulted from these principal infectious diseases last week, against 64, 53 and 68 in the three preceding weeks These deaths were equal to an annual rate of 1 8 per 1000, which was 2 5 per 1000 below the mean rate last week from the same diseases in the 76 large English towns The fatal cases of diarrhœa, which had been 20, 19 and 23 in the three preceding weeks, were 24 last week 13 occurred in Glasgow, three in Dundee, and three in Aberdeen The deaths from whooping cough, which had been 24, 21, and 22 in the three preceding weeks, fell to 19 last week, and included 12 in Glasgow and three in Edinburgh The fatal cases of measles, which had been six and 12 in the two preceding weeks, fell last week to seven, of which four occurred in Edinburgh The deaths from scarlet fever, which had been two and three in the two preceding weeks, were two last week These two deaths were registered in Glasgow The fatal cases of "fever,' which had been three in each of the two preceding weeks, were four last week, of which two occurred in Dundee The deaths referred to diseases of the respiratory organs in these towns, which had been 88, 49 and 75 in the three preceding weeks, fell last week to 55 and were 44 below the number in the corresponding period of last year The causes of 13, or more than 3 per cent, of the deaths in these eight towns last week were not certified

HEALTH OF DUBLIN.

The death rate in Dublin, which had been 17 9, 19 3, and 17 5 per 1000 in the three preceding weeks, rose again to 17 9 per 1000 during the week ending July 30th During the past four weeks the death rate has averaged 18 2 per 1000, the rates during the same period being 14 2 in *London and* 14 4 in Edinburgh The 130 deaths of persons belonging to Dublin registered during the week under notice showed an increase of three over the number in the preceding week and included 12 which were referred to the principal infectious diseases, against ten, 18, and 15 in the three preceding weeks, of these, four resulted from measles, four from diarrhœa, two from whooping cough, one from "fever," and one from diphtheria, but not any from small pox or scarlet fever The 12 deaths were equal to an annual rate of 1 7 per 1000, the death rates last week from the principal infectious diseases being 4 1 in London and 1 6 in Edinburgh The fatal cases of measles, which had been two, ten, and five in the three preceding weeks, declined again last week to four. The deaths from diarrhœa, which had been five, two, and five in the three preceding weeks, declined to four last week. The fatal cases of whooping-cough, which had been three in each of the two preceding weeks, were again two last week. There was one death from "fever," as against two in the preceding week. The 130 deaths in Dublin last week included 35 among children under one year of age and 18 among persons aged 60 years and upwards; the deaths of infants showed a considerable increase, while those of elderly persons were fewer than in any week during the present year. Six inquest cases and four deaths from violence were registered; and 50, or over 38 per cent., of the deaths occurred in public institutions. The causes of seven, or nearly 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon R. Miller to the *Terror* on recommissioning and for Bermuda Yard. Surgeons: J. C. Durston and G. E. Duncan to the *President* for hospital course.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel G. T. Trewman, half-pay, retires on retired pay (dated August 3rd, 1904). Major R. H. Clement retires on retired pay (dated August 3rd, 1904). Major G. B. Russell retires on retired pay (dated August 3rd, 1904). Major L. R. Colledge retires on retired pay (dated August 3rd, 1904). Major S. Butterworth retires on retired pay (dated August 3rd, 1904). Captain H. H. Norman is placed on temporary half-pay on account of ill-health (dated July 25th, 1904).

IMPERIAL YEOMANRY.

Oxfordshire (Queen's Own Oxfordshire Hussars): Archibald Henry Hogarth to be Surgeon-Lieutenant (dated July 30th, 1904).

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain W. A. Atkinson to be Surgeon-Major (dated July 23rd, 1904). Surgeon-Lieutenant J. R. Williams to be Surgeon-Captain (dated July 20th, 1904). Captain A. R. Badger, Worcester and Warwick Bearer Company, Royal Army Medical Corps Volunteers, to be Surgeon-Captain (dated August 3rd, 1904).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Cornwall (Duke of Cornwall's): Edwyn Graved Andrew to be Surgeon-Lieutenant (dated July 30th, 1904). 2nd Hampshire: Surgeon-Lieutenant-Colonel G. G. Sparrow resigns his commission and is granted the honorary rank of Surgeon-Colonel, with permission to wear the prescribed uniform (dated July 30th, 1904).

Rifle: 3rd Volunteer Battalion the Devonshire Regiment: Surgeon-Lieutenant E. R. Tweed to be Surgeon-Captain (dated May 15th, 1904). 5th (The Hay Tor) Volunteer Battalion the Devonshire Regiment: Surgeon-Major E. Haydon resigns his commission and is granted the honorary rank of Surgeon-Lieutenant-Colonel, with permission to wear the prescribed uniform (dated July 30th, 1904). 1st Volunteer Battalion the Suffolk Regiment: Brigade-Surgeon-Lieutenant-Colonel G. S. Elliston is seconded whilst holding the appointment of Senior Medical Officer of the Harwich Volunteer Infantry Brigade (dated July 30th, 1904). 2nd Volunteer Battalion the Worcestershire Regiment: Surgeon-Lieutenant H. B. Emerson resigns his commission (dated July 30th, 1904). 1st Volunteer Battalion the Duke of Cornwall's Light Infantry: Surgeon-Lieutenant F. Chown to be Surgeon-Captain (dated July 30th, 1904). 1st Volunteer Battalion the King's (Shropshire Light Infantry): Surgeon-Major F. K. Pigott to be Surgeon-Lieutenant-Colonel (dated July 30th, 1904). 1st Herefordshire: Surgeon-Major J. W. Hinings resigns his commission and is granted the honorary rank of Surgeon-Lieutenant-Colonel, with permission to wear the prescribed uniform (dated July 30th, 1904).

DEATHS IN THE SERVICES.

Staff Surgeon Henry Scanlan, R.N. (retired), at Kerswell, Broadclyst, Devonshire, on July 31st, aged 55 years. He entered the Royal Navy as surgeon in 1872, became staff surgeon in 1884, and retired in 1885. He served with the Royal Marine Battalion at Suakin during the operations in the Eastern Sudan in 1884-85. (Egyptian medal and clasp and Khedive's bronze star.)

THE NEW ARMY SCHEME.

Mr. Arnold-Forster's new army scheme will probably come before the House of Commons for discussion again on Monday next, when it may be hoped that some further information will be afforded and some additional light will be thrown upon the exact nature and extent of the new proposals.

MALTA FEVER.

We learn from India that a special commission is investigating Malta fever, the occurrence of which in India is becoming more recognised. A special committee is also investigating anti-typhoid inoculation.

FIFTY YEARS' MEDICAL SERVICES TO THE RUSSIAN FLEET.

The 20th of July was the fiftieth anniversary of Dr. V. S. Kudrina's official services as Chief Medical Inspector to the Russian Fleet and the occasion was taken by the Military Medical Academy to present him with a congratulatory address.

THE WAR IN THE FAR EAST.

Denatured spirit is finding a use at the seat of war. The chief Russian Military Medical Council has acquired a number of spirit lamps for the field hospitals fitted with special burners and giving a clear light. A parcel of these lamps has already been sent to the Manchurian army.

Lieutenant-General Linivitch says that he visited on July 24th the Nijnigorod and the Nijninovgorod hospitals at Chabarovsk in the Far East and found everything there a pattern of order and comfort. The hospitals are luxuriously furnished. He feels it his duty to thank the two towns on behalf of the army under his orders and to convey to the towns interested the expression of satisfaction their generosity has caused the soldiers. He gives unstinted praise to the staff, especially the two chief medical officers, Dr. Kossereff and Dr. Oschmana. General Kuropatkin, likewise, writes in praise of the Red Cross arrangements, especially mentioning the efficiency of the hospital furnished by the Kharkoff Zemstvo (local council) which he had personally visited between Lyao-yang and Saimatze.

The members of the St. Petersburg Society of Dental Doctors are arranging with their provincial colleagues with the object of opening at their common expense dental consulting and operating-rooms for the army in Kharbin, Mukden, Lyao-yang and other depôts of the Manchurian army.

The situation in the Far East changes from day to day, and we may at any moment hear of some great and striking success on one side or the other which may alter the aspect of the war. There has been heavy fighting south of Haicheng and at the present time the Japanese field forces are making a great and general advance; three of their armies are engaged and the Russians are probably hard pressed, while the position at Port Arthur has entered upon a very acute and perhaps final stage. As regards the general sweeping movement of the Japanese armies almost everything now depends on the success or failure of the first army in closing the net from the north-east. General Kuropatkin's position must be causing keen anxiety at St. Petersburg at the present time. The first official announcement from Tokio regarding the siege operations was made at the end of last month when the general staff announced that five officers had been killed and 41 wounded in the then recent fighting around Port Arthur, but the losses in men were not stated. As far as can be gathered from non-official reports all the public buildings inside Port Arthur are used as hospitals. The sick and wounded are stated to be well cared for by volunteer nurses. The wounds inflicted by the Japanese rifle fire are described as not dangerous except in vital spots. Hundreds of men after being badly wounded have quickly recovered and are now back in the firing line. The latest reports of the progress of the siege are not only very meagre but contradictory and untrustworthy. The Russian casualties at the battle of Tashichao are estimated by General Oku at 2000, while those of the Japanese in the entire engagement are put down at 1000, but little reliance can, as a rule, be placed in estimates formed in this way during a war. It is stated that there is much dissatisfaction in Russia at the relative absence of information as to the extent of the losses According to a war correspondent of the *Standard* a foreign merchant has arrived at Chifu who left Kharbin on July 22nd last and reports that during the last five weeks a very large number of Russian troops had arrived and were still arriving there They were well provisioned, grain was plentiful, the Russians paying good prices for it to the Chinese There were many wounded at Kharbin but there are excellent accommodation for them and ample medical comforts The Japanese prisoners have been sent to Tomsk where they are treated excellently The railway is working well, though slowly.

Correspondence.

"Audi alteram partem."

LAYMEN AND ELECTRICAL TREATMENT.

To the Editors of THE LANCET.

SIRS,—There are at least two sides to the question raised by "Fair Play" in THE LANCET of July 23rd. Amongst the reasons which lead many members of the profession to send their patients to laymen for treatment by electricity the following would, I think, occupy an important place. First, the expense. There are very few patients who care to pay a guinea, or even half a guinea, per *seance* for electrical treatment, possibly of many weeks' duration, or to pay from three to ten guineas for a skiagram Secondly, a medical man who thinks electrical treatment may be useful or at least worth trying in a particular case perhaps after he has exhausted other plans of treatment would often shrink from having his diagnosis and ideas of treatment overhauled by another practitioner

It is surely absurd to contend that there can be anything harmful to a patient in getting a skilled layman to skiagraph him for diagnostic purposes, although no doubt special anatomical knowledge is occasionally needful to interpret what is seen Again, "Fair Play" can hardly think that it is difficult for any skilled electrician who has an elementary knowledge of anatomy to apply galvanism or even high-frequency or static currents in a case, say, of sciatica, or to use the slowly interrupted faradic current in one of atony of the abdominal muscles I certainly think we should be careful to avoid sending our patients to the class of people who pose as "healers" or who prefer to act apart from medical men As a possible compromise I would suggest that the medical men who practise entirely in electro-therapeutics might employ nurses or other skilled assistants who could work under their supervision at a much smaller fee than they themselves are obliged to charge

I am, Sirs, yours faithfully,
E STANLEY SMITH
Wimpole street, W, July 26th, 1904

To the Editors of THE LANCET.

SIRS,—Apropos of the remarks made by "Fair Play" it is my firm belief that many men taking up electro therapeutics will when fully qualified refuse to register They will do so because if unregistered they will be assured of the support of their registered friends and can at the same time compete on an equal footing with the lay institutes in the matter of advertising, &c It is my experience that the generality of practitioners look upon electrical treatment as bordering on quackery They do so because the bulk of the work is done by laymen who, by business like methods, attract the public and force the medical man's hand

I am, Sirs, yours faithfully,
H VALENTINE KNAGGS
Camden road, N W, July 26th, 1904

THE SCOTTISH POOR-LAW MEDICAL SERVICE

To the Editors of THE LANCET.

SIRS,—While thanking you for your very kind congratulations on the successful settlement of my actions against the parish council of Durness I desire, with your permission, to put on record my high appreciation of the able and resolute manner in which the Medical Defence Union of London and its solicitors (Mr Hempson, London, and his Edinburgh agents, Messrs. Inglis, Orr, and Bruce, W S) have conducted this case to s[illegible] It is, I believe, [illegible] the passing of the [illegible] which established parish councils in place of the parochial boards and I trust that it may tend to hasten much needed legislation which will amend the aforesaid Act by giving to the parochial medical officers of Scotland a right of appeal against capricious or unjust dismissal by their parish councils, so placing the Scottish Poor law medical officers on a similar footing with their professional brethren in England and in Ireland I also desire to express my thanks to Mr W. L Muir, the energetic secretary of the Scottish Poor-law Medical Officers' Association, who writes to me as follows "You are to be congratulated on the result and the Medical Defence Union (London), of which you most fortunately are a member, are entitled to the thanks of the whole Scottish Poor-law medical staff"

I am, Sirs, yours faithfully,
JAMES F D. MACARA, M B, C M, Glasg.
Durness, Sutherlandshire, N B, July 26th, 1904.

LIVERPOOL

(FROM OUR OWN CORRESPONDENT.)

The University of Liverpool. the King's Visit to Liverpool.

ON the occasion of the visit of the King and Queen to Liverpool on July 19th Dr A W W Dale, the Vice-Chancellor of the University of Liverpool, was presented to His Majesty by the Earl of Derby and read a loyal address from the University, in which the gratitude of the governing body was expressed at the royal charter which had been granted to it The King, in reply, said that it was a source of sincere gratification to him to have been able to grant the charter to the University Though the period which had elapsed since the granting of the charter had been but short the efforts made for the advancement of knowledge by the authorities were deserving of the highest eulogy and would ultimately, he did not doubt, be rewarded by results worthy of so great a city

Death from Anthrax by Inhalation

A labourer at the Mersey Docks and Harbour Board's wool warehouse in Great Howard street, aged 62 years, returned home on July 19th and his wife noticed a small pimple on the left side of his lower lip which she considered to be a "blind boil" On the following day the man induced a barber who was shaving him to cut the point of the pimple. Later in the day the barber gave him some ointment to apply to it On the 21st the sufferer's face was swollen, but he went to his work nevertheless and experienced no pain. In the afternoon of the same day the keeper of the wool warehouse, *though not suspecting the ailment, induced the* sufferer to go to the David Lewis Northern Hospital where it was found that he was suffering from anthrax The face and the neck continued to swell and he died on the 24th An inquest was held by the city coroner and a verdict of "Death from anthrax" was recorded Dr. White, one of the house surgeons at the hospital, deposed *that the surgeons recognised* that the deceased was suffering from anthrax when he was admitted There was an ulcer on the face and the face was considerably swollen. The anthrax organism was found at the part where the pimple had been As the result of an operation the swelling was entirely removed and on the next morning the deceased was better On the night of the 23rd, however, he became rapidly worse and died on the following morning after experiencing acute abdominal pain. A post-mortem examination revealed a number of ulcers in the stomach which probably indicated internal anthrax The stomach was at the time under microscopical examination, but he had no doubt whatever that death was due to anthrax Mr R E. Graves, H M inspector of factories, who was present at the inquest, stated that this was the first fatal case from the inhalation of the germs of anthrax in Liverpool and he looked upon the stomach ulceration as important Mr. Graves said that Dr T M Legge of the Home Office, who was in court, had informed him that he had brought with him some serum which had been successfully used in other countries by way of injection against this disease and he was endeavouring to get it adopted by the medical profession in this country. It had had the effect of reducing the number of fatal cases. Dr. Legge intended to visit some of the hospitals in reference to the use of the serum.

The Renewal of the Lease of the Liverpool Medical Institution.

The question of the renewal of the lease of the Medical Institution (for which the estate committee of the corporation required £817) which had been a source of much anxiety to the trustees and council of the society for several months has at length been satisfactorily arranged. In 1880, when 40 years of the lease had expired, the appointment of new trustees to the institution owing to deaths had become necessary, and the council of the society applied to the corporation for a renewal of the lease free of fine as before. The application was granted at a peppercorn rent. However, a few weeks later the council of the society was informed by the town clerk for the time being that he considered it technically necessary to obtain the consent of the Lords of the Treasury prior to issuing the new lease, as it was proposed to grant it without fine. The Lords of the Treasury replied that they did not feel justified in giving their consent to the application as the lease would not have run out until 1915 and that no grievance could arise until then. In the meanwhile no action need be taken. On April 10th, 1902, the trustees of the society waited upon the estate committee of the city council, and in reply to an application for a renewal of the lease without fine they received the astounding intimation that a fine of £817 4*s.* would be required. This action of the estate committee was difficult to reconcile with the attitude of the corporation in 1881. A second deputation of the society waited on the estate committee later but without satisfactory result. Mr. T. H. Bickerton, the late treasurer of the institution and one of the vice-presidents, took the matter up warmly and read a most elaborate paper before the society on the History of the Liverpool Medical Institution in Special Relation to the Question of the Lease, in which he pointed out the admirable work which the society performed in the spread of specialised knowledge calculated to alleviate human suffering and to benefit the community at large. To his exertions and the sympathetic attitude of the town clerk the institution is indebted for the reduction of the demand made from £817, for the renewal of the lease for 75 years, to the nominal fine of ten guineas.

University of Liverpool: Admission of Graduates: Appointment to Fellowships.

On July 26th the third ceremony of admission to degrees took place in the Arts Theatre of the University. Amongst graduates of other faculties 16 gentlemen were admitted to medical and surgical degrees by the Vice-Chancellor, Principal Dale. Including admissions made on that day the Vice-Chancellor stated that of their Victoria graduates those who had actually taken advantage of the offer to become graduates of Liverpool the number was 342, of whom 307 had presented themselves in person, while 35 resided abroad and were admitted by special concession in their absence. What the Senate was trying to do was, so to speak, to build into the new fabric the stones belonging to the old one. The Gee fellowship on human anatomy was awarded to Dr. Hubert Gordon Thompson, the Johnston colonial fellowship to Dr. H. E. Roaf, the Ethel Boyce fellowship in gynæcology to Mr. E. Emrys Roberts, the Holt fellowship in pathology to Mr. H. Pierpoint, the Thelwall Thomas fellowship in surgical pathology to Dr. E. Cleaton Roberts, and the Stopford-Taylor fellowship in dermatological research to Dr. F. P. Wilson. Mr. P. Hick and Mr. F. R. Tickle were respectively awarded the Derby exhibition and the senior Lyon Jones scholarship.

Bequests to Liverpool Charities.

The late Miss Anne M. B. Hornby of Wavertree has bequeathed £500 to the Children's Infirmary and £100 each to the Woolton Convalescent Institution and the Nurses' Home, Dover-street.

August 1st.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Pauperism in South Wales.

STATISTICS relating to the amount and cost of pauperism in South Wales and Monmouthshire have recently been issued by Mr. F. T. Bircham, the Poor-law inspector of the Local Government Board. The population of this district in 1901 was 1,546,100, an increase of 221,054 over that recorded in 1891. In the whole of England and Wales 2·2 per cent. of the population were in receipt of parish relief on Lady Day, 1904, while on the same date in the six counties of South Wales and in Monmouthshire 2·7 per cent. of the population were being relieved, compared with 2·6 per cent. in March, 1903, and 2·5 per cent. in 1894. The lowest rate of pauperism was in the Bridgend Union—1·5 per cent.—and the highest in the Carmarthen Union—3·8 per cent. The cost of maintaining the indoor and outdoor paupers in the Bridgend Union was equal to 2*s.* 5¼*d.* per head of the population and in the Carmarthen Union 6*s.* 6¼*d.* In the Pontypridd Union the cost was 2*s.* 7¼*d.*, in Cardiff 3*s.* 9¾*d.*, and in Merthyr Tydvil 4*s.* 8*d.*

Public Abattoir for Dartmouth (Devon).

The Local Government Board inspector (Mr. E. A. S. Fawcett) recently held an inquiry into the application of the Dartmouth town council for permission to borrow £1050 to erect a public abattoir, about a mile from the town, on the summit of a hill. There was no objection raised to the proposal.

The Water-supply of Ilfracombe.

The new water-supply, which has been obtained for Ilfracombe from Exmoor at a cost of £55,000, was formally opened on July 27th by Lord Ebrington, the Lord-Lieutenant of Devonshire, in the presence of a large gathering.

The Winsley Sanatorium.

At the meeting of the Bristol city council, held on July 26th, it was decided, in consequence of some conditions laid down by the Local Government Board, to extend the period of time which the council will subscribe £1300 from one year to five years. The council, in addition, has also given £5000 towards the construction of the sanatorium. It is hoped that the institution will be opened in November and the Bath city council at its meeting on July 26th, on the proposition of the mayor, passed a motion asking the executive committee of the sanatorium to make special efforts to obtain the gracious consent of King Edward to perform the opening ceremony.

Celluloid Bound Bibles.

One of the Cardiff magistrates has provided for the use of the borough police-courts copies of the Bible bound in celluloid covers which can be readily cleaned. It is very rarely that a witness in the South Wales police-courts asks to have the Scotch form of oath administered.

The Three Counties Asylum, Carmarthen.

Upon their last visit to the Carmarthen Asylum the Lunacy Commissioners reported that there were 21 men and 13 women in the institution in excess of the proper numbers and suggested certain alterations in the old isolation hospital to make it in a fit condition for the permanent occupation of an increased number of patients. A dispute has been going on for many years as to the proportions of the contributions to be made to the asylum committee by the county councils of Cardigan, Carmarthen, and Pembroke and it was decided by the committee of visitors on July 28th that no matter entailing a large expenditure of money should be considered until the matters in dispute have been settled.

August 1st.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Dispensary Medical Officers.

THE salaries of the Poor-law dispensary medical officers in Ireland are notoriously insufficient, but the trouble caused by the careless issue of tickets, through which the medical officers are obliged to attend patients gratis under pain of dismissal, ranks in some districts as chief among the grievances. The "red ticket" is the chief cause of trouble, as the medical officer is expected to regard this ticket as an urgent command to visit a poor patient at his or her home. A recent example was brought before the Local Government Board and has been transmitted to the guardians of the Monaghan union. Mr. M. Halpenny, medical officer of Scotstown dispensary district in that union, requested that a "red ticket" forwarded to him should be cancelled on the ground that the woman whom he was thereby forced to attend was the wife of a rated occupier of a farm of 25 statute acres for which the farmer pays rent and taxes and possesses a vote. The woman was described on the "red ticket" as a labourer's wife The guardians at their meeting on June 27th refused to cancel it; hence the action of the Local Government Board in transmitting the medical officer's letter to them They have again postponed the matter. It would seem a gross case

The late Dr John Joseph Cranny.

The death of Dr John J Cranny of 17, Merrion square, Dublin, is much to be regretted He was widely known and very popular in the city, where his death at the comparatively early age of 59 years is keenly felt by the many friends who knew him and recognised his high qualities as a philanthropist and physician. He was the owner of considerable property in the Pembroke township where he represented for some years a district at the council board. Dr Cranny, who was a most charitable and retiring man, was an M D. of the University of Dublin, Fellow and member of council of the Royal College of Surgeons in Ireland, surgeon to Jervis-street Hospital and to the Orthopædic Hospital, and consulting physician to the Royal Hospital for Incurables

An Honorary Degree for Sir John W Moore

On July 28th the degree D Sc *honoris causâ* of the University of Oxford was conferred on Sir John William Moore, late President of the Royal College of Physicians of Ireland Professor Love, in presenting him to Convocation, said that the University welcomed in him a representative of the sister University of Dublin

The Belfast Hospital for Skin Diseases

At the annual meeting of the supporters of this hospital held on July 30th it was reported that during the year 926 patients had been treated and that the balance to the credit of the institution was £271 15*s* 10*d* The necessity of an improved Finsen lupus lamp was emphasised.

Ireland's Declining Population

The returns just issued of births, marriages, and deaths in Ireland for the ten years 1891–1900 are very unsatisfactory The population has diminished from 4,680,376 to 4,468,501—that is, there was nearly a quarter of a million fewer people in Ireland in 1900 than in 1891. In 60 years the population has declined from over eight millions to less than four and a half The tendency to a decline in the birth rate, which has become so marked in England, has also spread to the sister country, for the total number of births registered during the ten years was 1,055,020 as compared with 1,150,463 for the previous decade, being 95,443 (or 8 3 per cent) less The deaths during this decade were 836,035, as compared with 883,156 for the previous ten years, thus showing a decrease of 47,121 (or 5 3 per cent), but an *increase in the average* annual death-rate from 17 9 in the earlier to 18 2 per 1000 living in the later period It will be thus seen, looking at the diminished birth rate and the increased death rate, that the margin of national increase is rapidly declining Meanwhile the emigration continues The number of marriages registered during the period of these ten years was 221,608, or at the average rate of 4 84 per 1000 of the mean population, and there is a well marked decrease in early *marriages The number of illegitimate births* in Ireland (always exceedingly small and contrasting in this respect markedly with Scotland) shows still further diminution from 2 7 per 1000 in the decennium 1881–90 to 2 0 per 1000 in the decennium 1891–1900 The causes of the dwindling population of Ireland are of great interest but such a discussion is not exactly suited for a medical journal The influence of education is seen in these statistics, for it appears (looking to the number who "signed their names *in writing" as compared with those* who signed "*by mark*" in the marriage registers and certificates) that in 1864 61 4 per cent of the men and 49 7 of the women signed in writing, in 1871 the proportions were—men 62 5 per cent, women 54 8 per cent , in 1880 men 73 8 per cent, women 69 1 per cent , in 1890, men 79 6 per cent, women 79 1 per cent , in 1900, men 86 8 per cent, women 89 3 per cent It is a remarkable fact that, while there has been a steady increase in both sexes in the proportion signing by writing, the proportion among women, which was much below that for men in 1864, became equal to the rate for men in 1891 and has each year since exceeded it It is also curious to note that while in Leinster, Munster, and Connaught, taking the figures for each year of the decade, the married women seem to be better educated than the men, in Ulster the reverse was the case until the year 1900, when 85 5 per cent of the men and 86 3 per cent of the women signed their names in writing.

Nuisance by Gasworks

An important judgment was given in Dublin on July 28th by Mr Justice Barton The Belfast corporation was held to have injured a firm of linen merchants by smoke, soot, grime, and colly which issued from the corporation's gas retort house and injured and soiled linen goods on their premises situated on the opposite side of the street This looks like opening up a fine field for litigation

August 2nd

PARIS.

(FROM OUR OWN CORRESPONDENT)

The Epidemiology of Ulcerative Membranous Stomatitis

AT the meeting of the Academy of Medicine which was held on July 19th M Kelsch reminded his hearers that ulcerative membranous stomatitis, a disease which not so very long ago was epidemic in the army, only attacked young children and soldiers This point was an additional instance of the relationship between the pathological sensitiveness exhibited by these two classes There was a military pathology just as there was an infantile pathology and they were quite comparable The form of stomatitis in question only appeared in barracks during one century—viz, at the end of the eighteenth century. It remained sporadic until 1820, increased from then up to 1875, and then declined until it entirely vanished with the last years of the century As regarded the infantile form the course was similar It was very common and frequently epidemic in the Children's Hospital from 1830 to 1850 but since that date it had only been met with sporadically.

the oscillations which

the specific nature of

could only explain it

by connecting it with the attacks of sore throat due to fuso-spirillary bacilli which have been so common of late years and which in his opinion are due to a transformation of the organisms which formerly caused stomatitis of the ulcerative membranous variety.

Gastrostomy for Imperforate Œsophagus.

At the meeting of the Society of Surgery held on July 13th M Kirmisson read a paper on the case of a newly born child who had been taken to his wards in February of the current year suffering from an imperforate œsophagus. As is commonly the case in such instances of deformity, the œsophagus communicated with the respiratory passages *Within an hour or two of the admission of the* child to the hospital M Kirmisson attempted to perform gastrostomy but the stomach was so distended that it burst under the efforts of the patient M Kirmisson sewed the stomach to the abdominal wall, leaving an opening, but the infant shortly died A post mortem examination showed the rupture of the stomach had caused free hæmorrhage into the small omentum

Tuberculosis in Paris

A new dispensary has just been opened in Paris for the reception of members of the working classes of both sexes who have broken down from overwork and whom tuberculosis is on the watch to attack (*guette*) Over the entrance is inscribed, "*Prévenir, c'est guérir*" The treatment will consist in overfeeding and rest in the open air The chief of the dispensary is Dr Charles Richet

The New Hospitals

M. Mesureur, the director of the Assistance Publique, is pushing on the building of the new hospitals as fast as possible At Aubervilliers one block is already nearly completed The foundations of the nursing school at the Salpêtrière are dug but the new Pitié Hospital, which is to occupy the site vacated by the Salpêtrière, is scarcely begun, although the plans are definitely decided on The entrance to the new Pitié Hospital will be in the Boulevard de l'Hopital, opposite the general stores of the Assistance Publique Immediately inside the entrance are the reception room and the administrative buildings Then come the wards Two are allotted to surgery and two more, opposite to these, to medicine There is also a maternity block Later it is intended to build a third medical ward The nursing school will be finished n two years and the new Pitié Hospital in four years.

The Absence of "Anaphylaxie" in Man after Repeated Injections of Antidiphtheritic Serum.

At a recent meeting of the Hospitals Medical Society M. Marfan reminded the meeting that in two previous communications M. Arthus had pointed out that although the serum of a horse is not poisonous for a normal rabbit it becomes so for an "unguarded rabbit" (*lapin anaphylactisé*)—that is to say, for a rabbit which has been rendered hypersensitive by a repeated series of injections. After such a series of injections of five cubic centimetres of horse serum an œdematous infiltration is noticed at the seat of the latest injection, together with an aseptic abscess and patches of gangrene. A rabbit which has been rendered hypersensitive by six or eight injections, either given hypodermically or intraperitoneally will sometimes die in a few minutes if given an injection of two cubic centimetres by the vein of the ear. In other cases the rabbit shows acute toxic symptoms which, however, pass off for the time being, but the animal gradually becomes more and more cachectic and dies in a few weeks. A wide experience of injections of antidiphtheritic serum derived from the horse has enabled M. Marfan to state that this state of "anaphylaxie" does not exist in man, at least, in so far as regards hypodermic injections. Although the seat of injections sometimes shows swelling or redness, these phenomena are but transient and occur after one injection just as much as after many. There can be no question here of hypersensitiveness.

August 2nd.

Medical News.

UNIVERSITY OF LONDON.—At examinations held in July the following candidates were successful:—

M.D. EXAMINATION.

Medicine.—Hugh Barber, Guy's Hospital and Victoria University; Helen Beatrice Hanson, London (Royal Free Hospital) School of Medicine for Women; Arthur Charles Haslam, St. Thomas's Hospital; Septimus M. Hebblethwaite, St. Bartholomew's Hospital; Norris Norman A. Houghton, Guy's Hospital; Colin Dunrod Lindsey, St. Mary's Hospital; John Ford Northcott, Guy's Hospital; Claude Rundle, St. Mary's Hospital; and Richard Hamilton Townend, London.

Mental Diseases and Psychology.—William Ferris, B.S., St. Mary's Hospital.

Midwifery and Diseases of Women.—James Cole Marshall, St. Bartholomew's Hospital; Richard Drummond Maxwell, London Hospital; Thomas Massey Hospital; and George Struan Robertson

State Medicine.—Myer Copl[illegible] and Guy's Hospital.

M.S. EXAMINATION.

William Henry Bowen, Guy's Hospital; David Leighton Davies, M.D., University College; Walter Fedde Fedden, St. George's Hospital; Sydney Richard Scott, St. Bartholomew's Hospital; and Robert Gordon Strange, St. Thomas's Hospital.

UNIVERSITY OF EDINBURGH.—The following is the official list of passes at the recent professional examinations for degrees in medicine and surgery:—

First Professional Examination.—James Aiken, H. M. Anderson, A. H. T. Andrew, William Bainbridge, Alexander Baldie, Christina H. Barr, Margaret W. Bartholomew, Lydia D. la Trobe Bateman, Elizabeth M. A. Baxter A. R. Bearn, James Black, John Brander, Sarah E. Buyers, Ellison Causfield, J. T. Carson, Jean G. Cathels, P. H. Chauvin, D. G. Cooper, H. S. Cormack, F. G. Cowan, J. C. Craig, M.A., W. S. Crawford, Emilee C. Creaser, J. M. Dalrymple, Purser Davies, F. Dillon, A. E. Drynan, A. C. England, Cromwell Gamble, Thomas Gardner, Michael Gavin, Alexander Gibson, M.A. (with distinction), John Gilchrist, A. I. Girdweed, J. A. Gordon, A. T. Gowan, J. C. B. Grant, Robert Hannah, John Hewat, A. E. Huckett, P. F. Hugo, J. D. Ingram, K. R. K. Ivengar, Andrew Jamieson, J. A. Jamieson, F. E. Jardine, W. P. S. Johnson, R. Q. Jollie, E. W. Kirk, Robert Krause, F. R. Laing, C. L. Laurent, R. D. Laurie, H. R. Lawrence, D. C. Lee, Margaret M. Lindsay, V. D. O. Logan, G. H. Lowe, Robert M'Adoo, Margaret M'Cahon, Alexandra B. MacCallum, Ranald MacDonald, R. F. D. MacGregor, D. L. MacKenna, Kenneth Mackenzie, A. K. Maclachlan, W. M. Macnab, David Macnair, John Malloch, John Marshall (with distinction), Eva Meredith, W. A Miller, A. R. Milroy, J. A. Mitchell, V. P. Mondon, F. L. Moore, Anna L. Muncaster, William Murdie, M.A.; C. C. Murray, C. T. Newton, I. A. van Niekerk, A. C. Norman, C. A. Paterson, A. P. Pearson, J. H. Peck, H. R. A. Philp, Laura W. Pugh, F. W. Rayment, F. E. Reynolds, E. W. Richards, Charles Robertson, B.A., Marguerite Ross, Samuel Rowlands, D. H. Russell, C. S. Sandeman, W. A. Scobie, John Scott, R. L. Scott, Wilhelmina Sievwright, B. A., J. C. Simpson, J. T. Simson, E. W. Smerdon, Thomas Smyth, W. N. van Someren, J. E. Spence, R. H. Tait, J. J. Thomson, N. G. Thornley, Raymond Verel, F. H. de Villiers, A. A. Walbrugh, Dora M. Walker, E. A. Walker, W. O. Walker, L. E. B. Ward, W. H. te Water, F. W. Waterworth, A. P. Watson, M.A.; H. B. Watson, M.A., N. J. Watt, H. L. Watson Wemyss, E. V. Williams, Gordon Wilson, A. G. Yates, M.A., and W. A. Young.

Second Professional Examination.—G. P. Adshead, John Alexander, M.A., Alfred Arthur, A. F. Babonau, Ernest Banks, Frank Blamire, J. D. Bowie, H. F. Briggs, Alice M. Burn, Edward Burnet, B.A., W. P. Chrystall, J. A. Currell, J. S. Daniell, Richard Davidson, J. D. C. Duncan, J. S. Edwards, Mary S. Finlayson, F. S. B. Fletcher, K. N. Ghosh, J. E. Gordon, E. R. Grieveson, B.A., D. K. Henderson, W. M. P. Henderson (with distinction), Nettie D. Hendrie, J. M'Adam Hill, A. S. Holden, Spencer Jackson, W. W. Johns, W. T. A. Jolly (with distinction), R. Lloyd Jones, Beatrice Kippenberger, J. H. Lamb, S. B. Legge, John M'Cutcheon, A. T. M'Donald, George M'Mullan, W. J. Macnab, A. S. Mactavish, L. R. H. B. Marshall, A. H. M. Maxwell, J. E. Murray, Janet M. Murray, M.A., Meher A. D. Naoroji, A. J. P. Nowell, A. S. Paterson, Edith G. Pycroft, G. Y. Richardson, W. R. Ridley, W. G. Rivers, Graham Robertson, Thomas Robertson, W. O. Sclater (with distinction), H. L. Sells, Subrata Chunder Sen, E. D. Simson, R. St. C. Steuart, J. A. Taylor, E. W. Vaughan, A. S. Walker, and F. E. Wall.

Third Professional Examination.—Mukhtar Ahmed Ansari, A. W. Atkinson, A. J. [illegible] Norman Black, James Brennan, Gilbert [illegible] vn, B.Sc., J. S. Caldwell, Thomas Campbell, [illegible] Chisholm, F. W. Cragg, Davidina R. J. Davidson, [illegible], F. H. Dickson, M. G. Dill, James Dundas, David Eakin, H. F. Fenton, L. P. M. Gardner, H. S. Gaskell, E. G. Girdwood, J. A. Glover, M.A., E. J. C. Groves, J. T. Gunn, H. S. A. Hogg, G. H. Howe, J. H. Hume, J. F. James, J. R. Kerr, R. M. Liddell, John Lindsay, J. A. Loughridge, Peter M'Dermid, D. F. Mackenzie, William Magill, W. J. Maloney, J. A. Mathers, F. C. Mills, M.A., Harold Mowat, R. E. Moyes, E. B. Munro, R. E. U. Newman, R. H. Nolan, H. J. Norman, C. R. O'Brien, J. S. Orwin, J. L. Pearce, D. E. C. Pottinger, Gustav Raubenheimer, D. G. Reid, H. D. Robb, T. E. Roberts, J. R. Robertson, H. M. Sauzier, J. O. Shircore, E. M. Simmers, Archibald Simpson, W. Torrance Smith, W. J. Taggart, H. V. Taylor, J. H. du Toit, Andrew Wight, Richard Wilkins, C. R. Wills, and J. T. Young.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the July sittings of the Scottish Conjoint Board held in Glasgow the following candidates passed the respective examinations:—

First Examination (five years' course).—Alexander M'Murray, Belfast; John M'Kelvey, Belfast; Ernest Gibson, Cork; William Garfield Forde, Cloyne; Henry William Turner, Glasgow; Osmonde Rashleigh Belcher, Cork; Thomas Baird Ferguson, Kirkmaiden; Frank Humphry Ali Kiddle, Nellore, Madras; Patrick James Taaffe, Liverpool; John George Buchanan, Tiree; David Welsh, Wilsontown; and Karl Frederick Gorer, Demerara.

First Examination (four years' course).—George Vernon Edwards, Kendley, Cheshire.

Second Examination (five years' course). [illegible] Belfast (with distinction); John A [illegible] Garnet Allan, Whaley Bridge, Cheshire; [illegible] Kilmarnock; Joseph Hume Patterson, North Berwick.

Third Examination.—Alexander Brown, Galston; Percival Henderson, Skelmersdale; John Macnamara, County Leitrim; John M'Arthur, Calderbank; John Michael Moriarty, Co. Kerry; William Frank Hague Ive[illegible] [illegible]d Bolton, Dublin; Joseph Benjamin [illegible] rinidad, B.W.I.; and John Hughes Rol[illegible]

Final Examin[illegible] tiates of the Three Coöperating Authorities. [illegible]n, Carluke; Archibald Frank Greene Spi[illegible] Crothers, Banbridge, Ireland; Thomas Gr[illegible] khill; William Arthur Magill, Belfast; George Henry Waugh, Belfast; Llewellyn Charles Nash, New Shildon, R.S.O., Darlington; Percy James Thomson, L.D.S., Glasgow; Thomas [illegible] Henry Edward Strathy, Pitlochry; Reginal[illegible] Oswaldtwistle, Lancs.; Mathias Antonio Li[illegible] nburgh; John Hutchi[illegible]son Fyfe, L.D.S., Glasgow, [illegible] Edinburgh; and David Haig, Springburn.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGE OF PHYSICIANS AND THE ROYAL COLLEGE OF SURGEONS.—At the final examination the following candidates satisfied the examiners:—

With Honours.—James S. Sheill.

Passed in All Subjects.—Miss Alice M. Barry, Mathew Campbell, William J. Cowell, Michael Keane, William F. B. Loughman, [illegible] Lanigan O'Keiffe.

C[illegible] J. Bracken, George P. A. Bracken, Alfred [illegible] Crawford, [illegible] A. Cusack, Benjamin D. Gibson, George A. D. Harvey, Patrick Kinsella, Francis J. Lennan, William J. O'Sullivan, James Parker, and Thomas J. Ryan.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. Gustav Wolff of Carlsruhe has been appointed Extraordinary Professor of Psychiatry.—*Berlin:* Dr. Maximilian Henkel has been recognised as *privat-docent* of Midwifery and Gynæcology, Dr. Heinrich Poll as *privat-docent* of Comparative Anatomy, and Dr. Fritz Frankenhäuser as *privat-docent* of Internal Medicine.—*Bologna:* Dr. B. Schiassi has been recognised as *privat-docent* of Surgery.—*Bonn:* Dr. Wilhelm Reis has been recognised as *privat-docent* of Ophthalmology.—*Budapest:* Dr. J. Siklossy has been recognised as *privat-docent* of Ophthalmology and Dr. Illyes as

privat docent of Diseases of the Urinary Organs —*Constantinople* Dr Vollbrecht of Darmstadt has accepted the offer of the post of Medical Organiser of the Turkish Army in succession to Dr Rieder —*Copenhagen* Dr Wichmann has been appointed *privat docent* of Children s Diseases and Chief Medical Officer of the Queen Louisa Children s Hospital —*Erlangen* Dr Menge of Leipsic has been offered the chair of Midwifery and Gynæcology in succession to Dr Veit who goes to Halle —*Florence* Dr Lorenzo Bardelli has been recognised as *privat docent* of Ophthalmology —*Freiburg* At last the chair of Midwifery and Gynæcology, vacated by Dr Hegar, has been filled by the appointment of Professor Kronig of Jena —*Heidelberg* Dr Franz Nissl has been promoted to the chair of Psychiatry vacated by Dr Bonhoeffer who goes to Breslau Dr Siegfried Schoenborn has been recognised as *privat docent* of Internal Medicine —*Kieff* Dr A Shim
to the chair of Ophthalmology
Hammerschlag has been recog
Midwifery and Gynæcology —*Leipsic* Dr Wilms, *privat docent* of Surgery has been promoted to an Extraordinary Professorship —*New York (College of Physicians and Surgeons)* Dr Harry McM Painter has been appointed to the chair of Midwifery —*Turin* Dr Amadeo Herlitzka has been recognised as *privat docent* of Physiology

TORBAY HOSPITAL, TORQUAY —The necessary funds having now been raised for the provision of a children's ward and a new operating theatre at the Torbay Hospital Torquay, the work will be at once taken in hand

MEDICAL PROGRESS IN RUSSIA —A note from Rostov on the Don says that shortly a Pasteur inoculation station will be opened in the Nikolaevsk town infirmary The *Svet* announces that during the coming winter a pan Russian conference will be called of town sanitary educational institutions and veterinary surgeons to consider town sanitation and hygiene

SOCIETY OF MEDICAL OFFICERS OF HEALTH —At a meeting of the West of England and South Wales Branch of the Incorporated Society of Medical Officers of Health held at Oxford on July 29th Mr Ebenezer Davies was elected president of the branch Mr Davies was appointed medical officer of health of Swansea in 1864 and is probably the oldest medical officer of health in office in the United Kingdom

PRESENTATION TO A MEDICAL PRACTITIONER —Mr A R Johnston, M B, B Ch Dub who has resigned his appointment as medical superintendent of the infirmary of St Olave, Rotherhithe in consequence of ill health, after a connexion extending over 18 years, has been presented with a silver flower bowl and a pair of silver vases by officers and staff of the infirmary in recognition of his uniform attention and kindness on all occasions during his long tenure of office

The meeting then adjourned

EPSOM COLLEGE —On July 22nd the prizes were distributed to the scholars of Epsom College In consequence of a few cases of scarlet fever of a mild type having occurred during the last few weeks of term the school committee determined to omit the usual gathering of friends and parents of pupils on Founder s Day and as the outbreak took place so near the end of the term several of the boys went home beforehand The headmaster was enabled to say at the distribution that the strict measures of isolation and disinfection observed had resulted in no fresh cases occurring for 13 days The sanitary works and the disinfection of the College have been placed by the works committee in the hands of the local sanitary surveyor who has at his disposal the services of the College surveyor and contractor The latter will be carrying out the repairs and the cleansing of the College usually undertaken at the end of each term The emptying of the building for nearly two months will with the precautions already taken, give assurance that the College will be free from all taint connected with the recent outbreak Amongst the honours gained direct from the school since the last Founder's Day are an open classical scholarship of £80 at Keble College Oxford, and 11 passes at the last London matriculation examination, four boys being in the first division The honours gained by former pupils during the same period have been numerous and varied Dr Alan Reeve Manby has received the honour of knighthood, Mr H J Mackinder has been appointed by the senate of the University of London director of the school of economics and political science, Mr R C Lucas has been appointed headmaster of Wolverley Grammar School, Kidderminster, Dr L P Phillips has been appointed professor of clinical medicine in the Medical School at Cairo and physician to Kasr el Aini Hospital, Captain G T Mair has been appointed to the command of the Artillery of the Nigeria Frontier Force, Mr L S Wood has been appointed a junior inspector under the Board of Education, and Mr E M Corner has been appointed assistant surgeon to St Thomas s Hospital and to the Children s Hospital, Great Ormond street

CLOSING OF SCHOOLS IN SCOTLAND —The Local Government Board for Scotland has addressed circular letters to the medical officers of local authorities and to the clerks to local authorities on the subject of closing of schools on account of infectious disease The Board offers for their guidance some suggestions as to the considerations which ought to determine resort to such a measure The Board calls special attention to Article 30 of the Scotch Education Department Code and to the provisions of Section 57 of the Public Health (Scotland) Act 1897 The Board considers that the closing of a school is a serious interference with the educational work of a district and is not to be recommended or required as a matter of routine or for any but substantial reasons The medical officer of health must be

Vacancies.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

OVERCROWDING IN TRAINS.

A MEETING was held on July 28th at De Keyser's Royal Hotel, London, "to protest against the overcrowding of suburban trains and the dangerous neglect of the railway companies to provide proper accommodation and convenience for passengers." The Hon. Claude Hay, M P. for the Hoxton Division of Shoreditch, presided and explained that it was proposed to form an association to protect the interests of travellers. He disclaimed any desire to attack the interests of railway shareholders and believed increased facilities granted by the railway companies would result in larger dividends. The law on the subject was chaotic and required amendment. There might be legislative action in the next session of Parliament and therefore an organisation to focus public opinion on the matter was necessary. The Board of Trade officials had declared that it was the duty of the railway companies to enforce the by-laws against overcrowding. Captain Norton, M.P. for West Newington, said that the railway companies had a monopoly and had failed to fulfil their obligations. Resolutions were passed that immediate steps should be taken to secure the provision of those "reasonable facilities" that the law required, that the railway companies and other public carriers of passengers should be required to provide more adequately for the wants of travellers, and that a travellers' association should be formed with these objects in view and to protect the interests of travellers of every kind.

WANTED—A HOME.

M.B. (2) asks if any reader of THE LANCET can inform him of an institution into which a young man who is incapacitated by chronic asthma could be received upon payment of 12*s*. or 15*s*. a week.

A QUESTION OF ETHICS.

To the Editors of THE LANCET.

SIRS,—What is the generally accepted view on the ethics of the publication in popular lay periodicals by medical men of articles on medical and semi-medical subjects? Recently there appeared in two widely circulated monthly periodicals articles written, the one by the senior physician to a leading London hospital, another by a less well-known medical man. The former of these is worthy of a place in a medical journal. The latter is too "popular" in style. In their present situation they seem to earn the added letters "Advt."

I am, Sirs, yours faithfully,
M.B.

August 2nd, 1904.

*** We do not recognise the articles in question by our correspondent's description but it is difficult to lay down rules in such matters.—ED. L.

MUSSULMAN LONGEVITY—142 YEARS OF AGE.

THE *Kasbek Telegraph* reports the death at Samarkand of the Mullah Mohamed-Labir-Kasy-Domullah-Rassikoff, better known as Mullah Alyamiena. He was a Mussulman Methuselah, being at his death 142 years of age, at least so the press has announced.

◆

M.B. (1) is thanked for her letter. That the abuses which she details occur is undoubted, but the public health of the country is not entirely without supervision and tons of such unwholesome food are seized and confiscated yearly.

METEOROLOGICAL READINGS.

FRIDAY (12th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—5 P.M.: Mr. Armour: Abscess of the Brain.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1904, which was completed with the issue of June 25th, and the Title-page to the Volume, were given in THE LANCET of July 2nd.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1904 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address: THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

[illegible] insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31 Rue Bapts, Asnières, Paris.

An Address

ON

THE VALUE OF THE ADDITION OF CITRATE OF SODA TO COW'S MILK IN INFANT FEEDING.

Delivered at the Hospital for Sick Children, Great Ormond-street, on May 26th, 1904,

BY F. J. POYNTON, M.D. LOND., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

LADIES AND GENTLEMEN,—I dare to take up the threadbare subject of the artificial feeding of the infant only because I have the special object in view of introducing to your notice the value of citrate of soda. In order to do this it will be necessary very roughly to sketch in outline the difficulties which confront us in the feeding of the infant by artificial means and then to show when citrate of soda is likely to prove of use.

TWO PRINCIPLES IN ARTIFICIAL FEEDING.

When a child is taken from the breast or has never been put to the breast he has to be fed in some way or other. We naturally wish for a counterpart to human milk. Unfortunately we cannot obtain it. Nevertheless, we attempt to imitate it in some measure and are always trying new devices to obtain success. In this search there seem to be two rather different principles involved; true, they are not sharply demarcated from one another, but those who lean strongly to one or the other of them certainly differ to some extent in their methods. One of these principles always keeps in view that human milk is, what for need of a better expression I would call a vital fluid, meaning by this that its elements are very subtly blended. To this perfect blending of its elements those who keep this principle in view attach much importance. The other principle keeps in view the percentages of the chief elements in human milk and aims for a fluid which has the same percentage composition so far as its proteids, fats, and carbohydrates are concerned. It is true that these two principles are interwoven, but they determine rather different lines of treatment and imply a rather different mental attitude toward the problem.

Those who are impressed with the subtle composition of milk attempt to replace [illegible] s asses' milk or cow's milk, [illegible] Those who have faith in [illegible] f elements incline to the use of various forms of substituted milk and humanised milk. The former, when they are confronted with a case of infant atrophy from improper feeding, dwell rather upon the *nature* of the elements in the particular diet as being at fault, the latter dwell rather upon the *amount* of the elements in the particular diet—be they proteid, carbohydrate, or fat—as being at fault.

For myself, I attach more importance to the peculiar nature of the fluid that is used than to its percentage composition. It is certainly most important that we should know with some accuracy the percentages of the chief elements in human milk, but it is doubtful whether considerable variations in them make any real difference to a child with a good digestion. My sympathies are on the side of mothers who, when their infants are taking milk well, complain that they are not satisfied with food of such-and-such a dilution, which happens to be the rule-of-thumb dilution for that age. I should not tease such infants with more meals but, on the other hand, I should not be influenced in the least by a table of percentages. With a lack of faith in percentages and decimal points goes also a distrust of humanised milks—of milks with bovine bodies and human faces. I distrust them especially when they have been sterilised for long periods of time.

PRACTICAL DIFFICULTIES.

So much for these two principles; next for some practical difficulties. If we begin at the very beginning we must first compare the percentages of some of the chief elements in human and cow's milk, which are approximately:—

	Human milk.[1]	Cow's milk.
Proteids	1·5	3·0
Fat...	3·5	4·0
Carbohydrates	6 5	5·0

The differences in these percentages are clear enough and, it is well known that for infants cow's milk should be diluted and a little sugar and cream added. Unfortunately, often enough this dilution of the milk does not touch the real difficulty, which depends upon the differences between the digestibility of human milk and cow's milk—a difference, which depends in great part, though not entirely, upon the curd. Before touching upon this great difficulty, however, a few words upon the boiling of milk and its dilution are required. A healthy infant will thrive better on fresh cow's milk than on boiled milk. Unfortunately, in large towns we cannot promise a baby fresh milk. This is a penalty of civilisation and we have accordingly to make the best of circumstances. The more one thinks of this the more one is forced to see how impossible it is, except with extraordinary advantages, to feel sure that the milk in towns is safe. The many loopholes for contamination between the cow and the baby's stomach cannot at present in this country be stopped up, so we boil the milk, raising it to the boiling point for two or three minutes. The best diluting agent would appear to be good drinking water which has also been boiled; it is better, I believe, than either barley water or lime water.

Now comes the difficulty in the digestibility of cow's milk. Sometimes this is so great that to some infants it would appear to be almost a poison and in some of these cases it is interesting to trace an hereditary tendency to this idiosyncrasy. There is apparently some mysterious difference in the nature of cow's milk, which sometimes no alteration of the curd will put right, and for this reason I think it must always be that no one method for the artificial feeding of [illegible]

The dilution of milk makes the curd more digestible, but with this advantage there creeps in a frequent danger—in hospital practice a very real danger—namely, that of the over-dilution of milk. In correcting one fault there is the risk of incurring another. It is clear that although one may not be influenced very greatly by percentages it is essential that sufficient nourishment should be given to a child and if he has too little and too dilute food he will become flabby, anæmic, and prone to rachitis. Then, again, the milk which the poor get is often enough inferior, especially in fat, and this milk with dilution becomes insufficient for the child to make any real progress. It is so easy, too, to lose sight of this fact in a heavy out-patient department and as likely as not the mother will go blindly on, happy in the thought that the baby is not screaming with indigestion. In this hospital and in other children's hospitals this danger is guarded against by printed directions which are an inestimable boon to the community, though even these are lost or not read by the careless ones.

While dealing with this question of dilution it will be useful to give three more tables of percentages: one in which the milk has been diluted with two parts of water, one in which there are equal parts, and one in which there are two parts of milk to one of water. The numbers are as follows[2]:—

—	Human milk.	Cow's milk.		
		I. 1-2 of water.	II. Equal parts.	III. 2-1 of water.
Proteids	1·5	1·0	1·5	2·0
Fats	3 5	1·3	2 0	2 8
Carbohydrates	6 5	1 6	2 5	3·3

It is clear from these tables that even with two parts of cow's milk to one of water there is not enough fat. And yet

---

College, subsequently published in THE LANCET, I pointed out how seldom it was that infective cyclitis was met with. I was gratified to find from letters received that other ophthalmic surgeons, who had taken the trouble to inquire into their hospital records of recent years, were able to confirm the accuracy of this view. Since the year 1885, when I joined the staff of this hospital, two cases only of this disease have been under treatment. In the one many years ago the patient was a little girl who was admitted with a cystoid cicatrix following a perforating wound in the lower and outer quadrant of the corneo-scleral junction of the right eye. The injured eye had been treated elsewhere and had done well. The projecting loop of cicatrised tissue being very unsightly was snipped off with scissors and subsequently infective cyclitis supervened. The case was not mine. The second case occurred as recently as July, 1903, and as the notes thereof illustrate the present characteristics of the disease it will not be without interest to narrate them.

The patient was a woman, aged 62 years. She came to the out-patient department on July 23rd, 1903, with the history that for some weeks she had only been able to distinguish light from darkness with the right eye. She stated that in May, 1901, she was operated upon for cataract in the left eye at a London ophthalmic hospital. Unfortunately the eye went wrong and no recovery of vision resulted. When, therefore, she came to the hospital she was practically blind. Examination of the left eye showed a depressed linear cicatrix in the upper part of the corneo-scleral junction marking the situation of the section made for the extraction of the lens. Into this cicatrix the iris tissue had been dragged. The pupil was obliterated. The globe was slightly injected, tender on palpation, and tension was – 3. With regard to the right eye the ciliary and conjunctival vessels were deeply injected. On Descemet's membrane were numerous punctate opacities. The aqueous was turbid, the pupil was contracted, and the usual signs of plastic iritis were present. Tension was normal and the vision equalled perception of light. The patient was advised to come into the hospital at once for enucleation of the left eye. She, however, declined. But four days later she returned and was admitted. On the following day, July 27th, enucleation was performed. On the 28th the right eye was in a condition of *statu quo*. She was ordered on admission hydrargyrum cum creta four grains twice a day, guttæ atropinæ two grains every four hours, and chinosol fomentations twice daily to the right eye. On the 29th the patient was able to count fingers at eight inches. The aqueous was clear, the pupil dilating a little in the upper part. On the 30th Descemet's membrane was clear of dotted opacities. The ciliary and conjunctival injection was almost gone. The pupil was irregular but of moderate size. She could count fingers at one yard. On August 8th the pupil was in the same condition as recorded in the previous note. The vision equalled about $\frac{3}{60}$. The patient was discharged. At the time of her discharge the patient was so satisfied with the improvement in her vision that she has not shown herself since. I am therefore unable to record the further history of the case.

Let me next briefly pass in review some of the evidence bearing upon the infective nature of this disease. Ever since the introduction of Listerism infective cyclitis has become more and more a vanishing pathological entity. This is not due to the practice of over-zeal on the part of ophthalmic surgeons in sacrificing wounded eyes in anticipation of the onset of the disease. On the contrary, at no time more than the present has conservative ocular surgery been so paramount or, I may add, so justified by the gratifying results with which it is attended. The obvious inference, then, is that the present infrequency of the disease is directly due to the observance of the principles of Listerism. Furthermore, I think that the undoubted diminution in the virulence of infective cyclitis must also be attributed to the same beneficent influence. Not only are the attacks of the disease in the present day amenable to treatment but it is more the rule than the exception, as recorded cases have amply demonstrated, for good results to be obtained therefrom. The argument has been advanced that infective cyclitis is now a rare complication of cataract operations because surgeons exercise much more care in placing the position of their sections. This contention, however, has but little to recommend it. It might almost as equally be said that tetanus has vanished as an after-complication of operation wounds in general surgery because surgeons are more careful in their use of the scalpel. If the precise situation of a section for cataract extraction were the real cause of the rarity of infective cyclitis in the present day, how comes it that lacerated wounds of the ciliary region will heal kindly without any such complication provided that they are treated with strict antiseptic precautions? The inference is indisputable that the only safeguard against infective cyclitis is absolute antisepticism. Moreover, there is no reason for supposing that under such precautions the ciliary region or any other part of the eye will resent operative interference, or under normal conditions exhibit in these cases other changes than those which belong to natural processes of repair.

How, then, does it happen that infective cyclitis occurs? We are justified, I submit, in assuming that infection takes place either at the time of the infliction of the wound, operation or otherwise, or subsequently, before the processes of repair are completed. If we fully accept the infective theory of the disease another difficulty is smoothed out. A general belief prevails that so-called sympathetic ophthalmia and so-called sympathetic irritation are separate and distinct as morbid entities. It is not necessary here to discuss the reasons upon which this opinion is based. Suffice it, however, to say that this opinion has always seemed to me to be illogical and unsupported by any analogical facts. The so-called irritation can only be of infective origin and due to intermittent and small doses of toxin, insufficient to cause a full outbreak of the disease but yet sufficient to excite modified symptoms. To this hypothesis analogy from other diseases lends much support, into the illustration of which, however, it is not necessary to enter.

I have now said enough to emphasise my belief in the possibility of infective cyclitis becoming an almost unknown disease or of remaining in so modified a form as to cause but little anxiety either to surgeon or to patient. By our acceptance of the infective theory, although, of course, it still lacks bacteriological confirmation, we are nevertheless placed in the position of knowing how successfully to avert and combat the disease—a disease, be it remembered, which by its virulence in former days consigned so many a hapless patient to absolute blindness. Possibly a specific micro-organism of infective cyclitis may never be isolated, but what matters that when evidence so infallible leads to the sound induction of its presence and enables us to act accordingly? The failure so far to isolate it may be explained by the incompleteness of bacteriological technique. The conjunctival sac may be described as the dumping-ground of the host of micro-organisms which are met with in the human body. Apart from those which it receives from without, as from wind and dust, dirty fingers, soiled handkerchiefs, contaminated water, towels, and coat sleeves, it is kept well supplied by cultivations from the nose and lacrymal sac, not to mention the possibility of another source of supply as furnished by disease of the neighbouring bones and inflammation of their sinuses. In view, then, of the conjunctival sac forming so favourable a medium for the cultivation of such a complexity of micro-organisms, and the impossibility of sterilising it, the wonder is not that a disease of the nature of infective cyclitis should occur, but that any intra-ocular wound or operation should escape septic contamination. The probability is that the best course to pursue is to rely more on the mechanical removal of micro-organisms than on any attempt to insure complete sterilisation of the conjunctival sac; it is, then, for this reason that after each step in my intra-ocular operations the wound is thoroughly douched with a 1 in 4000 solution of chinosol.

RUSSIAN DOMESTIC SERVANTS AND MEDICAL EXAMINATION.—In St. Petersburg a bureau has been opened for the hire of domestic servants with obligatory medical examination of those hired.

METROPOLITAN HOSPITAL SUNDAY FUND.—The following are among the amounts recently received at the Mansion House for the Hospital Sunday Fund: Mr. George Herring (first instalment), £11,540; Holy Trinity, Kensington Gore, £133; St. Luke's, Redcliffe-square, £170; St. Margaret's, Westminster, £135; St. Andrew's, Fulham, £107; Brompton Parish Church, £172; St. Stephen's, Westbourne Park, £176; Emmanuel Church, Streatham, £91; St. Mary's, Aldermary, &c., £58; St. John's, Deptford, £60; St. John the Divine, Kennington, £66; Christ Church, Chelsea, £60; St. Philip's, Sydenham, £41; All Souls', Langham-place, £48; St. John's at Hackney, £30; St. Mark's Presbyterian Church, Greenwich, £35; Barnes Parish Church, £38: total, £60,000.

SUGGESTIONS FOR THE PREVENTION OF PUERPERAL INFECTION IN PRIVATE PRACTICE[1]

BY JOHN W BYERS, M A M D, M A O (HON CAUSÂ) R U I,

PROFESSOR OF MIDWIFERY QUEEN'S COLLEGE BELFAST PHYSICIAN TO THE BELFAST MATERNITY HOSPITAL AND PHYSICIAN FOR DISEASES OF WOMEN TO THE ROYAL VICTORIA HOSPITAL, BELFAST EXAMINER IN OBSTETRIC MEDICINE AND GYNÆCOLOGY TO THE ROYAL UNIVERSITY OF IRELAND

ONE of the special advantages of the annual meetings of the British Medical Association is that it affords an opportunity of hearing the views of medical men from different places on the various questions which may be brought forward for discussion in the sections, and surely no subject is of greater importance, alike from a national as from a professional point of view, than that of the prevention of those conditions, so often fatal which are due to puerperal infection. Since the introduction of the modern antiseptic and aseptic methods in the obstetric art an enormous improvement has taken place in the general results of midwifery practice. This is seen specially in the maternity hospitals. In my student days, and even in the early years of my practice, maternity hospitals were regarded by the public with the greatest suspicion. Puerperal fever was constantly breaking out in them and owing to this fact their wards had frequently to be closed and many members of the profession were in favour of abolishing altogether such institutions, while now all this is changed and there is no place in which a woman can be more safely located for her confinement than in a properly conducted maternity hospital. Of the many advances that I have seen since commencing practice nothing is more striking than the change brought about in the results of obstetric practice in lying in hospitals by the adoption of the antiseptic and aseptic methods. The following statistics from two Irish maternity hospitals (at one of which I received my midwifery practical training while I am now on the medical staff of the other) are noteworthy

1 *Mortality at the Rotunda Hospital*—During the last two years (ending Nov 1st 1902 and Nov 1st 1903) there were 3370 intern cases with 15 deaths, and 4233 extern cases with nine deaths, that is, out of a total of 7603 there were 24 deaths, or a mortality of 0 32 per cent and of these 24 deaths eight were due to sepsis (puerperal infection) that is a mortality of 0 1 per cent

2 *Mortality at the Belfast Maternity Hospital*—During the last two years (1902 and 1903) there were 638 intern cases with two deaths and 555 cases in the extern maternity with two deaths that is a mortality of four in 1193 cases or 0 33 per cent, and none of the deaths were caused by puerperal infection. Adding together the cases from these two Irish maternities we have a total of 8796 cases with 28 deaths, or a total mortality of 0 31 per cent, and a mortality from sepsis (puerperal infection) of 0 09

At both of these institutions midwives and students receive their practical training. The Rotunda Hospital in Dublin is the largest maternity in the British empire. The Maternity Hospital at Belfast is a very old one with 16 beds and an extern maternity, but a new and greatly enlarged institution with every modern appliance is at present in the course of erection in that city and will be ready next year. It will be of the greatest assistance in the training of students and midwives in practical midwifery

When we turn to private practice the brilliant results obtained in maternity hospitals it will be seen have not followed. Here are the latest available statistics on this question kindly given me by the Registrar Generals of England Scotland, and Ireland. I append them in the form in which they were sent

England and Wales—Death rates from puerperal fever (under which term are included deaths recorded from puerperal septicæmia puerperal pyæmia phlegmasia alba dolens and puerperal fever not otherwise defined) in England and Wales in the years 1900 1901 and 1902

Puerperal Fever

Year	Annual death rates— To 1 000 000 females living	To 1 000 000 persons living
1900	121	63
1901	122	64
1902	118	61

The figures for 1903 are not yet available.

Death rate in Scotland from Puerperal Septic Infection in the Years 1900 and 1901

Year	Deaths from puerperal septic infection	Death rate per 100 000 of female population	Death rate per 100 000 births
1900	225	10	171
1901	287	13	217

The figures for 1902 and 1903 are not yet available

Registration of Deaths Ireland

TABLE A —*Showing for Ireland the Number of Deaths from Puerperal Septic Diseases (including Phlegmasia Alba Dolens) of Females aged 15 and under 55 Years and at the undermentioned Age Periods comprised in these ages during each of the Three Years 1900 1902*

—	Deaths from Puerperal Septic Diseases in Ireland					
Year		years	years	years	35 and under 45 years.	45 and under 55 years
1900	235	2	28	131	72	2
1901	230	3	30	121	74	2
1902	220	7	25	112	73	3

TABLE B —*Showing the Rate per 10,000 of the Number of Females in Ireland of the respective Ages according to the Census of 1901 represented by Deaths from Puerperal Septic Diseases of Females aged 15 and under 55 Years and at each of the Age Periods as shown in Table A*

1900	1 853	0·084	1 234	3 902	2 892	0 091
1901	1 813	0 126	1 322	3 604	2 972	0·091
1902	1 734	0 294	1 102	3 336	2 932	0 137

TABLE C —*Showing the Rate per 10 000 of the Number of Married Women in Ireland of the respective Ages according to the Census of 1901 represented by Deaths from Puerperal Septic Diseases of Females aged 15 and under 55 Years and at the Age Periods as shown in Table A*

1900	4·937	11 506	9 257	8 549	4·616	0 155
1901	4 891	16 959	9 918	7 896	4 744	0 155
1902	4 678	39 570	8 265	7 309	4·680	0 233

The figures for 1903 are not yet available

The number of deaths from puerperal septic diseases in Ireland also represent 23 3 22 8 and 21 6 per 10 000 births registered in the years 1900 1901, and 1902 respectively, and 5 3 5 2 and 5 0 per 100 000 of the estimated population of both sexes at all ages

In my presidential address delivered at the opening of the section of Obstetric Medicine and Gynæcology at the annual meeting of the British Medical Association in Cheltenham July 31 t 1901 I gave the statistics of mortality from puerperal fever in England and Wales, Scotland and Ireland for the five years 1895–99 inclusive. While the above figures give the mortality in obstetric practice it must always be recollected that there is another test besides (1) absence of mortality as an indication of successful midwifery work, and that is (2) absence of morbidity, by which we mean milder forms of puerperal infection recognised clinically by slight feverish attacks and having underlying pathological lesions, such as cellulitis, salpingitis or salpingo-ovaritis, and slight attacks of phlegmasia alba dolens—conditions which lead sometimes to secondary sterility and often necessitate subsequent gynæcological treatment.

---

[1] A paper read in the Section of Obstetrics and Gynæcology at the Oxford meeting of the British Medical Association on July 28th 1904

The difference in the results in these two sets of statistics indicates that the chief mortality takes place outside maternity hospitals—that is, in general practice; and it is corroborated by Dr. W. Williams (medical officer of health to the Glamorgan county council) who, in his Milroy lectures, "Deaths in Childbed: a Preventable Mortality," recently delivered before the Royal College of Physicians of London,[2] shows "that during the last 20 years, when a more accurate registration has been adopted, upwards of 40 per cent. of the total childbed mortality has been caused by septic diseases." The 20 years are from 1881 to 1900. It is also a remarkable fact that during this period of undiminished puerperal mortality sanitation has made rapid strides and that both the occurrence of, and the mortality from, such diseases as typhoid fever and tuberculosis have gradually diminished, while "the mortality of lying-in institutions, both in their internal and external departments, has also decreased to the vanishing point" (Williams). These facts, as well as the circumstance pointed out by Dr. Williams that notwithstanding the precautionary measures adopted in general midwifery practice 4000 mothers are annually lost in England and Wales (speaking generally, it may be said that the deaths from accidents of childbirth and puerperal fever, as shown by the statistics of death registration, amount to about 4·7 per 1000 births and almost one half of these are due to puerperal infection; for example, there were in the year 1901 in England and Wales 2079 deaths from puerperal fever and 2315 deaths from other causes—accidents, &c.), as well as the statistics I have given, naturally raise the question, Why is it that the results of private midwifery practice are not so good as those obtained in maternities? I may be allowed to answer this by asking three questions:—

1. Is the practical teaching of students and midwives in obstetric work as thorough as it should be? Are midwives taught to appreciate fully all that is now known as to the causation of puerperal infection and the grave responsibility that this knowledge brings upon those engaged in that line of practice? Why is it that the licensing bodies demand from students evidence of having had a clinical training and a practical experience in midwifery so much less than what is required in the subjects of surgery and medicine? Is there not a risk that, owing to the introduction of so many new subjects in the medical curriculum, some of the older branches which lie at the foundation of practice, such as obstetrics, are being neglected?

2. Are we as careful (and this applies to both nurses and medical men) in carrying out the details of the antiseptic and aseptic methods in private practice as in maternity hospitals?

3. Is there not often too much meddlesome interference in obstetric practice?

Before venturing to make any practical suggestions for bringing the results of private midwifery practice more into line with what is now the rule in maternity hospitals, it may render this task easier if we first consider certain facts which throw a light upon the nature of puerperal infection.

1. In at least 75 per cent. of midwifery cases labour is a natural physiological process, occurring in such a manner that nothing more than a certain amount of care—expectant watchfulness—is required and no interference is needed.

2. A woman who delivers herself spontaneously and who has never been examined internally rarely has any signs of puerperal infection. Leopold was the first to show this when he pointed out that at the Dresden Lying-in Hospital of a series of 248 cases who were delivered without medical aid, who were neither examined, touched, nor syringed, 98 per cent. had no fever during the puerperium. Five only had febrile symptoms and they were slight. This observation has since been frequently confirmed by others.

3. Women who enter a lying-in hospital after delivery—that is, those confined on the way to the hospital—rarely suffer from puerperal infection because, through not having been examined internally, they have avoided the risks of having the germs which cause the disease conveyed to them. This fact has been observed frequently by those connected professionally with maternities.

4. The uterus and vagina in a pregnant woman who has not been examined internally contain no pathogenic organisms but, as has been demonstrated by Whitridge Williams of the Johns Hopkins University, they are present upon the inner surface of the labia and the margins of the hymen in at least 60 per cent. of pregnant women, and the mere introduction of a sterilised glass speculum two centimetres in diameter, which he points out is no larger than the two fingers employed for examination, carries microorganisms into the vagina in at least one-half of such cases.

5. The results of midwifery practice become better the less vaginal examination and the more abdominal palpation is used.

6. *Vaginal examinations during labour are always attended* with risk and should never be employed unless to elicit information for the welfare of the patient which cannot otherwise be obtained by abdominal palpation. It must never be forgotten that a patient in labour who has not been examined internally is almost absolutely safe from the risks of puerperal infection.

7. Puerperal infection is due to the introduction of microorganisms which may be found on the patient's vulva, her clothes, bed, instruments, and the hands and clothes of those who look after her; hence the importance of disinfection of the patient's vulva, of a clean bed and clothes, of *disinfection of all instruments and of the hands of her* attendants who should wear sterilised overalls or clean, freshly laundried towels pinned carefully so as to prevent their own clothes coming in contact with the patient. Care should be taken that in the case of an internal examination, the hands after being disinfected do not become fouled again by touching the bed, clothes, vulva, &c., before entering the vagina. In making a vaginal examination (the vulva having been previously washed with soap and water and rinsed with a corrosive sublimate lotion 1 in 1000) the disinfected thumb and forefinger of the left hand are used to hold open the vagina so that the fingers of the right hand, previously sterilised, pass direct from the basin of perchloride lotion into the parts without touching the inner surface of the labia or hymen. The same care and precautions should be taken in sterilising the hands in obstetric as in surgical work. These facts suggest certain precautions which must be observed if we are in private practice to prevent the occurrence of puerperal infection.

I. Nurses and students should be taught clearly the risks of vaginal examination and the great value and absolute safety of replacing this method by abdominal palpation. So far back as 1886 Credé wrote—"Even the simplest manipulation may cause infection. It should therfore be laid down and taught as a fundamental principle that internal examination of parturient women should be altogether avoided or restricted within the narrowest possible limits. It can be very well replaced by external examination. To instruct their pupils as thoroughly as possible in this method is the present and future duty of *teaching institutions*." Have we teachers done our duty in this respect? Is it not too often the case that reliance for diagnosis is placed on vaginal examination alone employed as a mere matter of routine to see how the labour is proceeding, while the danger involved in such a method is not fully realised. I can only say—as a personal contribution—that I was taught by others the vaginal *method and that subsequently I taught myself the abdominal* plan of examination and the more I use this latter method the greater I appreciate its value. The man or woman who employs this method will, I am confident (and such has been the experience with students in maternities), be more accurate in his or her diagnosis and will rely less and less on the vaginal route. In many confinements during the past few years I have not made a single vaginal examination, as the external plan gave all the information required, and the only thing one cannot yet be sure of is prolapse of the cord when the membranes rupture. If in a normal case an internal examination is to be made at all the best time is just after rupture of the membranes. I regret very much that in the "Directions to Midwives," framed by the Central Midwives Board, no reference at all is made to the importance of abdominal palpation, although candidates are required before being admitted to an examination (pages 8 and 24, Rules of Central Midwives Board) to produce a certificate certifying that they have attended and watched the progress of not fewer than 20 labours, making abdominal and vaginal examinations during the course of the labour, and personally delivering the patient, and among "Duties to Patient," No 8 (p 15), "no more internal examinations should be made than are absolutely necessary" is ambiguous as it raises, without answering, the question, How many are absolutely necessary? and, by omitting any notice of the abdominal method it tends to emphasise the fact that the vaginal examination is the only method to be employed I now meet often at confinements nurses who are wonderfully skilful in abdominal palpation and personally I prefer to recommend to my patients midwives who make no vaginal examinations ' Dr R D Purefoy, whose term of office as Master of the Rotunda ended on Oct 31st, 1903, and who very kindly supplied me with the statistics from that institution, writes me "In most of the cases in the hospital *no* vaginal examination is made In some *one* is made Where necessary, of course, this is repeated " I am not prepared to deny that a woman who has never been examined at the time of her confinement may subsequently develop sepsis I have seen such cases and Dr Purefoy tells me that at the Rotunda "in some of the fatal septic cases no vaginal examination had been made before the trouble arose,' but such cases are extremely uncommon and may be due (1) to the introduction of the gonococcus shortly before labour; (2) contact by the patient's fingers touching the genitals, (3) contact with dirty clothes or a dirty bed, and (4) Whitridge Williams's account of the bacteriology of the inner surface of the labia minora and hymen shows how easily a wound there in a natural labour might allow pathogenic organisms to enter Still, admitting all this, the results of modern maternity hospitals show beyond question that vaginal examinations are the main source of puerperal infection

---

[2] THE LANCET, June 18th (p. 1701) and 25th (p. 1772), and July 2nd (p. 4) and 9th (p. 64), 1904.

II Nurses and students should be taught more and more clearly the cause of puerperal infection—viz, that it is introduced from without, and also the importance of keeping themselves and the patient aseptic and how extremely easy it is for the disease to be introduced

III It should be clearly recognised that in at least 75 per cent of the cases labour is a natural process not to be interfered with and that, as has been well stated by a recent writer (Edgar), "the whole process of labour properly considered, is a conservative process, the tendency of which is to prevent sepsis and it should be our aim not to thwart this process or supplant it by methods of art but to follow and aid it, interfering only, when, for one reason or another, the resources of nature prove inefficient" It was a well known saying of the older school of obstetricians that "meddlesome midwifery is bad," and surely vaginal examinations unless when clearly indicated, the uncalled for use of the forceps, early rupture of the membranes, douching unless in very special circumstances, and any interference with the third stage of labour (such as manual removal of the placenta) are all examples of meddlesome midwifery When, however interference is necessary during the course of labour the same precautions should be taken as regards patient, instruments and our hands and arms as are now employed in abdominal operations Attention has been drawn by several writers recently to the midwifery bag as being a "weak point in the obstetric defence of the woman in labour against the assaults of sepsis" (Ballantyne) I can recommend the following plan which I have used for the past five years with the best results After the use of the forceps or any other instrument it is carefully washed with soap and water and a nail brush, dried, and rolled up in a towel or paper and taken home without being replaced in the obstetric bag It is subsequently sterilised at home by boiling, dried with a sterilised towel, and placed in a sterilised bag which is put in the large midwifery bag When required at a confinement it is taken out of its own sterilised cover and placed in boiling water before being used

There are three other precautions which are of considerable importance as preventing indirectly the occurrence of puerperal infection

1 The careful general examination of pregnant women is important, so that at an early date we may detect a flaw in any of the organs (heart, kidneys, lungs), the knowledge of which may lead to the adoption of a judicious prophylactic treatment and so maintain the patient's strength and health and resisting power.

2 A few weeks before the expected date of the confinement—especially in a primipara—a careful abdominal examination should be made, so that we may learn the presentation and position of the fœtus, the amount of liquor amnii, and the presence or not of an abdominal tumour, and if there is the least suspicion of deformity the pelvic cavity should be measured

3 The immediate repair of any laceration of the pelvic floor following delivery is a most important point in the prevention of puerperal infection

Such, in brief, are the suggestions which, if fully and fairly carried out, would, I venture to hope, soon make a marked change in obstetric practice and bring the results of private midwifery work more into line with the brilliant records now achieved in properly conducted maternities.

Belfast

NEPHRITIS IN INFANTILE SCURVY

By GEORGE F STILL, M A, M D CANTAB,
F R C P LOND,
ASSISTANT PHYSICIAN FOR DISEASES OF CHILDREN KING'S COLLEGE HOSPITAL ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN GREAT ORMOND-STREET

THE occurrence of hæmaturia in infantile scurvy is now well recognised, it is also recognised that when hæmaturia is not present a trace of albumin in the urine may apparently represent a slighter degree of the same abnormal vascular or blood condition, whatever it may be, which determines the occurrence of hæmorrhage in scurvy Both these abnormal characters of the urine are, I believe, much commoner than has been supposed, indeed, so far as my own observations go, it would seem to be the rule rather than the exception to find that the urine in any case of pronounced infantile scurvy contains either a trace of albumin or blood But this hæmaturia is evidently simply part of the general hæmorrhagic tendency of scurvy, there is nothing whatever to suggest that it is due to a nephritis, the urine is not characteristic of renal inflammation, and when albumin is found without blood it is almost always so slight in amount that it certainly could not be accepted as *per se* evidence of nephritis The term "hæmorrhagic nephritis' applied to these cases of simple hæmaturia in infantile scurvy seems to me a misnomer, even when, as in one recorded case,[1] "a single granular cast was found on two occasions' The two cases recorded here seem to be of interest as showing, so far as can be shown from clinical evidence alone, that infantile scurvy may produce not merely albuminuria or hæmaturia but actual nephritis

CASE 1 —A girl, aged 11 months, had been wasting for two months For eight months before the wasting began the infant had been fed on unsweetened condensed milk and for the last two months had been fed on fresh milk boiled and mixed with Allenbury Food No 3 When seen by me (Feb 10th, 1903) the infant was much wasted, the skin was sallow and very dry, the legs looked "puffy' especially over the feet, but there was no definite pitting on pressure There was no tenderness of the limbs which were moved freely There were two upper and two lower incisors present and the gums around these teeth were greatly swollen and deep violet purple a very typical example of the gum affection in infantile scurvy The urine at this time was slightly red, showed many blood corpuscles, some leucocytes, and on boiling with acetic acid there was "a moderate cloud of albumin", no casts were seen On Feb 19th, after eight days of treatment with potato cream, orange juice, unboiled milk, and raw meat juice, the gums had almost entirely lost the purple discolouration and were much less swollen and the infant was said to be "much brighter" No further specimen of the urine was obtained until the 20th, it was then no longer red and only a few blood corpuscles were found with the microscope, the amount of blood had greatly diminished In spite of this diminution, however, the albumin had greatly increased and formed a flaky precipitate on boiling with acetic acid Microscopic examination showed, without centrifuge many tube-casts, granular, hyaline, and epithelial Although the scorbutic condition of the gums was so much improved and the infant's general condition decidedly better there was still considerable illness and the skin remained dry and harsh. There was no œdema now or at any time. On the 26th the urine still contained a large amount of albumin; with the microscope blood corpuscles were found with difficulty, the number of tube-casts was less, but hyaline and granular casts could still be found easily without centrifuge. The infant was now much better in every way. On March 4th the infant seemed quite recovered from the scurvy but there was still "a cloud of albumin" on boiling with acetic acid. From this date onwards no casts were found but a slight cloud of albumin persisted, and when the infant was last seen, 16 months after the scurvy, there was still a constant trace of albumin in the urine.

---

CASE 2.—A boy, aged eight months, had been fed on the Allenbury foods since the age of four weeks (except for a period of six weeks during which he had Benger's food made with cow's milk). The Allenbury foods had been continued until a fortnight previously when sterilised milk was given and a little raw meat juice. One month ago it was noticed that the feet and legs became tender and that he did not move his legs about. A fortnight ago his left eye suddenly showed swelling and redness of both lids which a few days later had the bruised appearance of "a black eye." Seen by me on April 28th the infant showed marked proptosis and outward displacement of the left eye. He cried piteously when the legs were moved. There was slight hæmorrhage in the gum behind the one lower incisor which was present. The child was pale and seemed ill. There was no general œdema. Treatment was begun at once with potato-cream, orange juice, &c. On May 3rd a specimen of urine was obtained and showed on boiling with acetic acid a flaky precipitate of albumin which was evidently much more than could be accounted for by the few blood corpuscles discovered by the microscope. There was a large number of casts, epithelial, granular, and hyaline, seen without centrifuge. On the 8th all the tenderness of the limbs had gone and the proptosis of the eye was much less. On the 20th a second specimen of urine obtained showed no blood but some albumin and still epithelial and granular casts, but not nearly so numerous as before, and only found with the centrifuge. On the 23rd the urine still showed a definite cloud of albumin on boiling with acetic acid but there were no casts. The infant now seemed quite well. On June 9th there was still a trace of albumin in the urine but no blood and no casts.

The difficulty of obtaining specimens of urine and the small amounts available in both these cases made the record of the urinary condition much less continuous and less complete than one could have desired; both the infants were treated at home and I am much indebted to the kindness of Dr. A. G. Jones of Harlesden in the one case and to Dr. R. M. Fraser of Ilford in the other case for opportunities of watching the course of the renal affection. Perhaps the most noteworthy feature in these two cases of nephritis with infantile scurvy was the latency of the nephritis. Apart from examination of the urine there was nothing to lead one even to suspect the presence of nephritis. This, of course, is not peculiar to nephritis with scurvy; it is noticeable in nephritis with various other conditions, for instance, I have recently had under my care a child, aged four and a half years, with pneumococcal empyema, whose urine was found quite unexpectedly to be very albuminous and to contain a very large number of granular and epithelial casts, although there was nothing in the child's appearance or in the symptoms to suggest any renal disease. The possibility of such latent nephritis makes routine examination of the urine desirable in all cases of infantile scurvy.

The relation of the hæmaturia to the nephritis in these cases is not very clear; the marked diminution of the hæmaturia which was present in the first case before any evidence of nephritis appeared in the urine rather suggests that the blood may have been due partly or entirely to the hæmorrhagic tendency of scurvy, not to the nephritis. The acute stage of the nephritis, as judged by the quantity of albumin and the presence of casts, was of short duration in both these cases; in the former casts had disappeared within 12 days after the onset of nephritis; in the latter they were absent 20 days after the renal affection was first noticed; but as might be expected the damage to the kidney is more lasting when this nephritis has occurred than in the common cases of simple hæmaturia or albuminuria with infantile scurvy. In both the present cases a trace of albumin persisted in the urine long after the infant had completely lost all symptoms of scurvy, in the latter for at least some weeks, in the former for at least 16 months.

The relation of the nephritis to the infantile scurvy must remain undetermined until we have more exact knowledge of the pathology of scurvy. At present any views on this point can only be speculative. It may perhaps be contended that the occurrence of nephritis in infantile scurvy points to the presence of some materies morbi rather than to a mere deficiency of some normal constituent in the blood—in other words, that it indicates a positive rather than a negative fault as the cause of infantile scurvy. Even on the assumption, however, that nephritis implies some such irritant it by no means necessarily follows that scurvy is due to a similar irritant, be it ptomaine, toxin, or micro-organism. The nephritis may equally well be secondary, due perhaps to toxic products of the disturbed metabolism in scurvy, which disturbance itself may be due—and in my opinion probably is due—solely to a negative fault—the absence of certain food-constituents from the diet. But it may not be necessary to assume any such irritant as the exciting cause of the nephritis. It has been pointed out by Sir Thomas Barlow that interstitial hæmorrhages are sometimes found in the kidneys in fatal cases of infantile scurvy and these, I would suggest, may entail a certain amount of inflammatory reaction which when the hæmorrhages are sufficiently numerous or extensive may produce the ordinary evidences of renal inflammation in the urine.

Harley-street, W.

"INTERRUPTED CIRCULATION" AS A THERAPEUTIC AGENT,

ILLUSTRATED IN TWO CASES OF RHEUMATOID ARTHRITIS.

By WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE BELGRAVE HOSPITAL FOR CHILDREN.

IMPROVED union of fractures was obtained by Hugh Owen Thomas (1876)[1] by "damming the circulation" above and below the lesion. This practice had previously been revived from Ambroise Paré[2] by v. Dumreicher[3] or perhaps rediscovered by him, as Paré's method did not include any compression below the lesion. These results and the good effects derived in various affections, including joint affections, by Professor August Bier (1894)[4] from a "continuous passive hyperæmia" induced by slight compression of the veins[5] above the part affected, taken side by side with the benefit secured in the following cases by working on an opposite principle, show that the same therapeutic ends may sometimes be attained by different means. All these observers used the tourniquet *to the veins only* (and therefore, most important to note though not mentioned, to the lymphatics also) with a view to increasing local nutrition by vascular overcharge. The principle of treatment to be described in this communication has an equally wide range of application to the various tissues, including the extravascular tissues, but its mechanism is an imitation not of an abnormal circulation, but of the healthy circulation with its afferent pressure-waves of nutrient blood and its efferent suctional stream of denutritive juices. Both these forces are artificially intensified by rapid alternations of capillary flushing and of capillary emptying. The tourniquet is applied intermittently (for periods of one half to two minutes, repeated several times at a sitting); and sufficient pressure is used to close *the arteries* after draining the limb by elevation and stroking.

Artificial anæmia, kept up for periods of five minutes, seems to have been the essential feature in the cure of a case of Raynaud's disease by the tourniquet reported upon the physiological 'blocking effect of the elastic constriction on the peripheral vasomotor nerves The simpler view seems to be that the emptied arteries suddenly receive a ramming charge when the tourniquet is removed and that the internal surface of the capillaries and of the lymphatic spaces in which they are immersed is submitted to sudden stimulation, whilst on the other hand, during the preceding stage of ischæmia a certain amount of suction must have existed within them not only owing to the collapse of the elastic tissues, but also from the intravascular negative pressure set up by the procedure The tendency would be for the emptied blood vessels to suck up some of the remaining tissue lymph, or in cases of inflammation some of the more fluid inflammatory exudates Of these two actions that of the forcible arterial flushing and that of the suctional tissue drainage it is hard to say which might be the more efficient therapeutic agent in affections of inaccessible tissues such as bone bone marrow, articular cartilages and synovial membranes In rheumatoid arthritis with its special features of immobilisation of the joints and of stagnation of the lymphatic circulation they would both fulfil direct indications, and it has proved to be so in the cases to be narrated But a variety of other tissues and of other conditions might be equally benefited and in addition to any further observations in the e wider fields of work I shall hope to hear of the larger experience of others

[5] Bier (loc. cit., p. 16) was also one of the earliest advocates of "active hyperæmia" by the application of hot air, &c.; 1891.

The technique which was employed is exceedingly simple A padded armlet of soft leather or failing this a circular pad of lint and cotton wool of sufficient thickness to protect the nerves, having been secured round the upper arm or the thigh a loop of indiarubber tubing of suitable thickness is passed behind the limb over the pad and the two ends of the loop are strongly put on the stretch with one hand The other hand immediately grasps the tubes close up to the front of the limb thus tightening the loop into a strong ligature or tourniquet The degree of arterial occlusion depends upon the strength with which the two ends of the loop are pulled up the limb having previously been drained of much venous blood by raising it and by stroking the larger veins empty The compression has for its effect quickly to induce cutaneous blanching and numbness of the extremity, similar changes doubtless taking place through the thickness of the limb For ordinary purposes half a minute or at most two minutes of this will suffice The tube is then let go, and this is at once followed by a bright cutaneous flush of capillary injection and a pleasant feeling of warmth The same manœuvre is then repeated say six times at intervals of a few seconds Two or more such sittings may be used daily The method is so simple that I have been able to intrust its application to my nurses To them as well as to my able house physicians, Mr P F Tinne and Mr P A Hayne I am indebted for their most valuable assistance In both the cases the results hitherto obtained have been most satisfactory but their advanced articular and periarticular changes and the resulting articular stiffness cannot be got quite well short of a much more protracted course of treatment

CASE 1—This case was exhibited before the Harveian Society in May, 1904 when the method was demonstrated The right wrist had been selected for treatment because it was so much worse than the left more thickened much more painful, and almost absolutely stiff The first and each subsequent application gave great relief to the constant soreness and pain which entirely ceased after a few days The swelling and synovial effusion also gradually lessened until they were less than in the left wrist which, however, still remains the more mobile of the two The patient a girl aged 17 years (Medical Register, No 214) was admitted on Feb 6th 1904, into St George s Hospital as a case of relapsing acute rheumatism She had first been seized 11 weeks before and again after a short period of improvement two weeks prior to her admission The ankles and knees had been slightly affected and the wrists permanently affected from the first She was placed under the usual treatment by salicylate and iodide and milk diet, but the improvement was not satisfactory and the temperature continued to oscillate above normal until after three weeks she was made to lie out of bed and was given tonic treatment abundant food, and some port wine, with passive movement and iodine applications to the wrists Though April 26th with such good effect that on the 28th it was ordered to be used twice daily, with six turns of half a minute each at each sitting It was then and has continued to be limited to the right wrist in order to afford a basis for judgment Whilst much of the improvement in the patient as regards appearance strength, and weight (the weight has gone up from 6 stones 2 pounds to 7 stones 11 pounds) is to be ascribed to the general treatment adopted the striking relative improvement which has occurred in the right wrist cannot be explained except in connexion with the special local treatment which it has received It now presents hardly any soft swelling and the fluorescent screen shows a distinct view of the carpal bones previously blurred This point having been clearly established the same treatment will henceforth be used for both wrists and there is a good prospect of their ultimate complete recovery

CASE 2—This was a case of chronic crippling osteosynovitic rheumatoid arthritis of both wrists originating in a gonorrhœal attack 11 years ago in a coachman, aged 39 years who was admitted on May 3rd 1904 into St George s Hospital (Medical Register No 685) Both feet had been originally affected disabling him for 12 months He broke his right wrist two and a half years previously and a second attack of ' rheumatism about two years ago settled in the knees and in the hands Since last December the hands had gradually become worse, but he kept on the box until two days before admission when swelling of the right knee caused him to lie up On admission he was found to be suffering from a gonorrhœal discharge with synovitis of the knee and with chronic changes and stiffness of both wrists which were massively enlarged and also presented much baggy effusion The usual forms of treatment were adopted and in view of his gouty tendency he also was prescribed colchicum ite well soon after the cessation a return of the latter the left and was cured by local treatment and by curing the urethritis Meanwhile no improvement was perceptible in the wrists and on May 24th the treatment by interrupted circulation' was begun The right wrist was selected for treatment because it was so much more swollen and much more rigid partly in connexion with the old fracture The treatment was well borne produced no discomfort but after two or three applications considerable alleviation of the aching and of the swelling At the present time the right wrist is almost quite free from the synovial swellings which are still present in the other wrist (not treated by this method) and though still massive and misshapen it has regained a limited range of movement which is daily increasing under passive motion The subacute effusion in the right knee was also treated with decided benefit by the same method and it was possible to verify in it by fine measurement the diminution in size brought about by separate applications It is noteworthy that during the last few days the patient has spontaneously undertaken for himself and successfully carried out the application of the india rubber tube tourniquet to his right arm A continuance of this treatment and of the hot water massage seems likely to bring about a return of considerable mobility in the crippled joints

Remarks—In both these cases the synovial and lymphatic effusions have appeared to me to have been benefited more largely than the peri articular fibrosis, and this is consistent with the views expressed as to the probable mode of action of this method But in the treatment of the stiffness of joints there is a definite help in the numbness which accompanies the stage of ischæmia and which allows, within prudence an increased amount of passive motion to be applied The method would therefore be specially promising in the early stages and in the exudative forms of rheumatoid arthritis it being understood that it is merely an adjunct in our treatment from which we cannot spare any other available resource whether local or constitutional

Rheumatoid arthritis however as previously stated is only one of many conditions both medical and surgical likely to be benefited by interrupted circulation The following N S Lambert[7] has resorted a constricting elastic band to ation with the object of preventing gangrene in a case of ligature of a wounded femoral artery. Another surgeon, L. Isnardi[8] of Turin, finds that the application of an Esmarch's bandage before changing the dressings of large wounds or burns obviates the distressing pain and bleeding otherwise unavoidable. Other developments will doubtless follow in the department of medicine and in connexion with cutaneous affections. But it remains a problem whether, and in what form, the principle may be made available for other districts than those of the limbs. In conclusion, I gratefully trace to H. Cushing's paper the original impulse and to George Oliver's most instructive work much of the growth of this thinking.

Curzon-street, W.

AN EPIDEMIC OF ACUTE OPHTHALMIA.

BY SIMEON SNELL, F.R.C.S. EDIN.,
OPHTHALMIC SURGEON, ROYAL INFIRMARY, SHEFFIELD; PROFESSOR OF OPHTHALMOLOGY, UNIVERSITY COLLEGE, SHEFFIELD.

EPIDEMICS of ophthalmia attacking large numbers have at different times been recorded. These have often been connected with military establishments or other institutions where people have been congregated together. The disease in these epidemics has been trachoma or granular ophthalmia and the disastrous and far-reaching effects of this dire disease have been well exemplified in many such outbreaks. Other epidemics of less severity have also from time to time been recorded. In 1894[1] I related at some length particulars of an outbreak of ophthalmia in a good-class boarding school which affected large numbers and led to the temporary breaking up of the school. A well-known surgeon who was called in after I had first reported on the outbreak was of opinion that the disease was trachoma. The sequel, however, showed the correctness of my first opinion that it was a less serious disease and that it was more of the nature of that described by Fuchs and others as follicular conjunctivitis. Those interested in the subject of epidemic ophthalmia may find the account of this outbreak and the means adopted for its eradication worth perusal.

The outbreak now to be described is, so far as I am aware, a rare and unusual one both from the numbers affected and the character of the disease. It spread very rapidly and in such a way that admitted of no question of its contagiousness and quickly subsided when measures to combat it were adopted. Everyone seeing much of ophthalmic practice, especially among hospital patients, is accustomed to observe instances of muco-purulent or catarrhal ophthalmia and is aware also how highly contagious a disease it is. Not infrequently several members in a family will be afflicted. A case coming under observation leads to inquiry as to others being affected and to instructions being given for preventing the extension of the disease. It is very rare, however, for the affection to spread in a community to such numbers as was the case in the outbreak which I am about to describe.

On May 5th of the present year I received a communication from Dr. H. Peck, medical officer of health to the Chesterfield rural district sanitary authority, informing me that a serious outbreak of contagious ophthalmia had occurred at Staveley, one of the townships of his district, and desiring me to consult with him as to the nature of the epidemic and the steps to be taken to eradicate it. On the day following we accordingly met at Staveley. A large number of cases were gathered together in one of the schoolrooms for examination. Before, however, referring to these it will be well to give some particulars of the outbreak and of the sanitary aspects of the district. Staveley is a township with about 12,000 inhabitants and Dr. Peck informed me that the district was a very healthy one. The first case of ophthalmia occurred about three months before our visit and since that time others had appeared in the same district and later in other parts. Recently the number affected and the absentees thereby of children from school had rapidly increased. The sanitary inspector had, therefore, specially reported the matter to Dr. Peck on May 5th. Those mostly affected were children, but the epidemic implicated people of all ages, amongst whom was a female teacher. The Staveley elementary schools are national schools and the number of children attending them was given me as follows: boys, 328; girls, 240; and infants, 400. In addition, the Roman Catholic schools accommodated 180 children. There was no evidence of overcrowding in the schoolrooms and Dr. Peck, who frequently visited the schools, had no fault to find with the cubic space. The intercourse of the children occurred in the schoolrooms and playgrounds. There was a washing place in the boys' school but it was in a separate building. Any boy requiring to use it was obliged to obtain the key from the master and consequently not one a week applied for it. This arrangement, though open to objection on some grounds, for the purpose of our present inquiry excluded the propagation of the disease at the boys' school either by towels or washing basins. In the girls' school there was a washing place in the lobby and it was therefore more used. It has been mentioned that a large number of those afflicted were brought together for examination. These exemplified the characteristics of the epidemic and showed how widely spread it was. Altogether 24 families were represented. In many instances one or other of the parents attended with their children, in others the children came by themselves. The cases examined and the evidence ascertained as to other members of the same families disclosed a total of 68 afflicted, and practically the whole of these had occurred within the previous fortnight. Some interesting information was obtained as to the numbers affected in different families. Frequently one or other of the parents, usually the mother, had been affected as well as the children. In two families five children and the mother had suffered, in another six and the mother, whilst in one no less than ten children and the mother had been afflicted. The prevalence in other families was noted as follows: four children and the mother, three children and the mother, three children and the father, and three children alone.

The fact that the sanitary inspector, with the help of the schoolmaster and school attendance officer, was able at less than 24 hours' notice to collect this large number of afflicted families gave unmistakeable evidence of the widespread extent of the epidemic. It appeared an inside estimate to say that 200 persons must have been afflicted with the disease. Dr. Peck wrote me later to say that on the day following our examination he had come across nine additional cases attending other schools. The character of the disease was the same in all—muco-purulent or catarrhal ophthalmia. The cases examined were in various stages of the disease; some were very acute, with swollen eyelids and free discharge of flakes of muco-pus, whilst others had passed through this stage and the thick discharge had ceased. In no case was the cornea implicated. On the day following this examination, however, I saw a woman from the same district suffering from the disease. It was very acute in both eyes and the discharge was plentiful. The cornea in one eye was affected. Her recovery was, however, excellent. In all the cases both eyes, so far as I could learn, were affected. The Koch-Weeks bacillus was found with the microscope but attempts to obtain cultures failed. This failure with cultures, I understand, is not infrequent even when the bacillus is detected with the microscope. The specimens for examination were taken from the woman just referred to in whom the disease was in the acute stage and was typical of the outbreak.

The investigation at Staveley thus clearly established the nature of the disease, its extremely contagious character, and the widespread prevalence of the epidemic. It will have been noticed that the great bulk of those afflicted were children of school age. They were, whilst the disease was acute, physically unfit for school and had been usually kept at home by their parents. It did not appear, therefore absolutely necessary for the present to close the schools and I reported to the sanitary authority that if other measures were at once adopted it was to be hoped that the epidemic would cease without resort to such a procedure. It was pointed out that many of the cases examined were in a very acutely contagious condition and all the others were more or less so and that it was necessary to recognise how very contagious the disease was. The smallest particle of the discharge reaching a healthy eye would speedily affect it. Many of the cases were fortunately making a good recovery but it was necessary to bear in mind that in others sight might be endangered and that therefore the need for treatment should not be forgotten.

The following suggestions were made: 1. That a notice should be issued by the medical officer of health setting forth the contagiousness of the disease and the necessity for separation, as much as possible, of the affected from the healthy children The importance should be urged of the use of separate towels, handkerchiefs, &c. Linen used for the children's eyes should be destroyed Parents before and after giving attention to the children's eyes should be careful to wash their own hands It was better for the children to wash with running water at the tap than from basins. The disease might be spread by others using the same water which one affected had previously used 2 Any child suffering from the disease should be kept from school and not allowed to return until all discharge from the eyes had ceased 3 The necessity for treatment should be pointed out to the parents and they should be advised to apply to a medical man as soon as the disease commenced Speedy treatment would not only avert the disease and its danger but would also shorten its duration and tend to prevent the spread of it 4 The importance of preventing the children using the towels in the schools was impressed upon the schoolmaster and this would doubtless be carried out

[8] Ibid., June 22nd, 1904.

[1] Brit. Med. Jour., Nov. 17th, 1894.

With the greatest promptitude after our consultation Dr Peck issued a printed notice which admirably expressed the salient points It ran as follows —

ACUTE CONTAGIOUS OPHTHALMIA

These notices were posted in different parts of the district and distributed by means of the scholars of the seven schools within three miles of the affected area The warning given to, and the distribution of 1500 of these handbills by, the scholars no doubt aided very materially in limiting the spread of the epidemic A zone was formed beyond which it was thought the disease was not likely to extend It is satisfactory to note that the means adopted were successful and that the epidemic was soon at an end Fresh cases arose but with less frequency On June 6th, a month after our visit, the schoolmaster wrote saying that the attendance officer had not heard of any fresh cases and that he himself had only noticed two cases recently Dr Peck informs me that he saw two cases on June 7th which were then subsiding Since that date he has neither seen nor heard of any others *I feel that much is due to Dr Peck for recognising* the seriousness of the epidemic and for the promptitude with which he aided in the adoption of measures for its eradication

THE PREVALENCE OF CANCER AND ITS INCREASE

BY W ROGER WILLIAMS, F R C S ENG

IT *is stated that as the result of its investigation into this* matter the Imperial Cancer Research Fund has come to the conclusion that the data upon which the mortality statistics are based indicate that there has been no real increase of cancer As I believe this conclusion is entirely erroneous I now propose to challenge it with a direct negative and in support of this position I beg to submit the following evidence which, after weighing the subject in all its bearings, seems to me to be absolutely conclusive

PRELIMINARY REVIEW

In the course of organic evolution some types of disease—like species—have diminished and become extinct while others have increased and become more prevalent In comparatively recent times plague, typhus fever, leprosy, malaria scurvy, and dysentery have almost or quite disappeared from our country small pox and other zymotic diseases have greatly diminished while phthisis and other tuberculous affections are decidedly on the wane On the other hand, a small group of maladies, of which cancer is the chief, have steadily increased, and this in spite of progressive diminution in the general death-rate Of the other members of this group insanity, suicide, alcoholism, and diabetes are the chief, while to these may be added diseases of the circulatory system, premature births, and congenital deformities Coincidently with these changes the population has slowly increased, *having hardly doubled in 65 years During the period from* 1840–1901 the cancer mortality has increased nearly five-fold—viz , from 177 per 1,000,000 living to 842 In all modern civilised communities a similar tendency is noticeable, especially as regards cancer, the incidence of the malady doubling in frequency in periods of from 20 to 30 years This tendency seems to be of comparatively recent origin At any rate, cancer is a disease of great antiquity and is known to have existed from the most remote times of which we have any record The "Papyrus Ebers," which is believed to have been written about 1550 B C , contains a short section on malignant and other tumours, from which it may be inferred that the cardinal features of these maladies were then well recognised In the works of Hippocrates—who is supposed to have flourished during the latter part of the fifth century B C —malignant and other tumours are referred to In the somewhat detailed enumeration of the *various maladies prone to occur at the different periods of life* which is embodied in the Aphorisms" no mention is, however, made of cancer From this omission and from the comparative paucity of the references to cancer in the Hippocratic writings I conclude that this affection must then have been comparatively rare We have but little trustworthy information as to the prevalence of cancer in England during the Middle Ages and at earlier periods, yet it is probable that it was then of much less frequent occurrence than in recent times The exceptionally well-kept registers of Market Deeping (Lincolnshire) during the years 1711 to 1723, in a total of 387 deaths, show only two from cancer (one male and one female)

STATISTICAL SUMMARY

In the very earliest years of registration, before the enumerating machinery had been perfected the data elicited may have left something to be desired We will therefore commence our study with the year 1840 when the national statistics, under the able guidance of William Farr, had already acquired well deserved reputation for reliability In that year 2786 persons died from malignant disease in England and Wales, the proportion being 1 in 5646 of the total population, 1 in 129 of the total mortality, or 177 per 1,000 000 living In 1901 the deaths due to this cause numbered 27 487 being 1 in 1186 of the total population, 1 in 20 of the total mortality, or 842 per 1,000 000 living In this respect the position occupied by malignant disease is unique, for no other malady can show *such a great increase Whatever the etiological factors of* cancer may be it is thus evident that they are not constant in action and if capable of exacerbation in some circumstances they may be amenable to diminution in others In further illustration of this subject I have compiled the following table which shows the decennial increments of increase during the long succession of years

Year	Total population	Total deaths	Cancer deaths	Cancer death rate per 1 000 000 living	Proportion to population	Proportion to total deaths.
1840	15 730 813	359 687	2 786	177	1 to 5646	1 to 129
1850	17,773 324	368,995	4 966	279	1 „ 3579	1 „ 74
1860	19 902,713	422 721	6,827	343	1 „ 2915	1 „ 62
1870	22,501 316	515 329	9 530	424	1 „ 2361	1 „ 54
1880	25 714 288	528 624	13 210	502	1 „ 1946	1 „ 40
1890	28 762 287	562,248	19 433	676	1 „ 1480	1 „ 28
1900	32,261 013	587 830	26,731	828	1 „ 1207	1 „ 22

THE REALITY OF THE INCREASE

With these figures before us, *and all that they imply,* there can be no doubt as to the reality of the increase in the cancer mortality Yet this has been called in question The earliest objectors ascribed the registered augmentation to mere increase of population, but the futility of this quibble is demonstrated by the fact that while the population has barely doubled (1850–1900) the cancer mortality has trebled Next the attempt was made to explain the increase as due to the average age of the population having advanced and the consequent liability of greater numbers To this the answer is that the saving life in modern times has mainly been confined to the pre cancerous years of existence, the death rates of males over 35 and of females over 45 having remained almost stationary, while the numbers attaining old age has decreased. Hence, only an infinitesimal fraction of the increased cancer mortality can be thus accounted for. Moreover, an increase in the cancer mortality is by no means a necessary corollary of the survival of augmented numbers to the cancer age, as the Irish mortality statistics show. Another objection to the reality of the increase in cancer has been raised by Dr. A. Newsholme and his followers. They maintain that the registered increase is only apparent, being due to improved diagnosis and more careful death certification. There is, however, far too much uniformity in the steadily progressive increments of increase during the long succession of years to furnish any warrant for such a suggestion, while taken in its entirety the increase is so enormous as to make this explanation seem quite far-fetched. Moreover, if improved diagnosis and death certification have caused additions to the cancer total—which I do not deny—these same conditions have also caused subtractions from it. Thus, as the Registrar-General tells us in his fifty-fifth report, even up to the year 1880 such common diseases as "fibroid tumour," "polypus," and "lupus" were usually classed as cancer. In like manner many other morbid states formerly often regarded as cancerous are now relegated to other categories. It is hardly likely then that there is any validity in Dr. Newsholme's contention which, as I will now proceed to show, is—in its main contention—a statistical sophism, based upon fallacious figures as well as upon fallacious reasoning.

It is claimed that there has been no increase in the registered cancer mortality for those parts of the body in which the disease is readily "accessible" and therefore presumably easy of diagnosis, such as the uterus, the mamma, the tongue, the mouth, &c., whereas in "inaccessible" localities, such as the stomach, the liver, and the intestines, where diagnosis is presumed to be difficult, the increase is very marked. It is maintained that the greater increase of the male as compared with the female mortality may thus be accounted for, owing to the incidence of the disease in men being of preponderant frequency in so-called "inaccessible" localities. In support of this hypothesis reference is made to some data derived from the Scottish Widows' Life Assurance Society and to mortality statistics of Frankfort, but, as Dr. J. F. Payne[1] has pointed out, these seem to be a very inadequate basis on which to raise such a superstructure. Before accepting any such conclusion we must inquire whether similar results are arrived at in larger populations and under more representative conditions. In the report of the Registrar-General for 1889 a table is given with the object of determining this very question by analysing a certain representative selection of the deaths from cancer during the years 1868 and 1888 respectively. The results thus obtained with regard to localisation may be epitomised as follows:—

MALES.

Per 100 deaths from malignant disease.

	1868.	1888.
Stomach	35·3	24·0
Liver	12·0	14·9
Tongue and mouth	8·0	7·2
Rectum	7·3	8·9
Face	6·3	3·2
Intestine (ex rectum)	4·0	6·6
Pharynx, tonsil, &c.	2·5	1·9
Lip	2·2	2·0
Bladder	2·1	3·1
Extremities (upper and lower)...	2·1	2·0
Penis, testis, and scrotum	2·0	1·6
Jaws	1·7	2·9
Œsophagus	1·8	4·9
Abdomen	1·5	2·7
Prostate	0·6	*Nil*
Mamma...	0·2	0·2
	90·1	86·1
All others	9·9	13·9
	100·0	100·0

FEMALES.

Per 100 deaths from malignant disease.

	1868.	1888.
Uterus	38·0	31·4
Mamma	24·2	18·3
Stomach	11·9	11·9
Liver and gall-bladder	6·4	12·7
Rectum	3·7	4·8
Intestine (ex rectum)	2·1	5·3
Abdomen	1·7	2·8
Tongue and mouth	1·5	0·7
Face	1·5	1·2
Pharynx and tonsil	1·0	0·7
Extremities (upper and lower)	1·0	0·6
Œsophagus... ...	0·7	1·3
Jaws	0·7	0·6
Bladder	0·6	0·8
	95·0	93·1
All others	5·0	6·9
	100·0	100·0

The net result of this inquiry was to show that the increase of the disease had not been confined to one or to some few parts of the body but that it had involved them all. It is specially noticeable that cancer of the stomach, the chief representative of the "inaccessible" group, shows less relative augmentation, especially in males, than any other local variety of the disease; and—in both sexes—the death-rates from this form of cancer show less increase than those for cancer in general. Thus, in 1868 the death-rate for cancer of the stomach per 1,000,000 living, 35 years old and upwards, was—for males 283·65 and for females 193·45, whereas in 1888 the figures were—for males 346·15 and for females 277·75. Thus, the increase for males in the 20 years was 22 per cent. and for females 44 per cent., but during the same period the death-rate for cancer in general increased 50 per cent. So far, therefore, as this analysis goes Dr. Newsholme's postulates are shown to be untenable. Since the year 1897 Dr. J. F. W. Tatham has introduced into the Registrar-General's annual reports a table showing the localisation of the disease for each year. Analysis of these tables for the years 1897 and 1900 respectively gives the following results:—

MALES.

Per 100 deaths from malignant disease.

	1897.	1900.
Stomach...	20·6	20·5
Liver	14·2	13·9
Rectum	8·6	9 0
Tongue and mouth	6·3	6·8
Intestine (ex rectum)	6·3	7·0
Œsophagus	5·7	5·4
Bladder	3·3	2·8
Jaws	3·0	2·3
Neck	2·7	2·3
Pharynx, tonsils, &c.	2·3	2·2
Larynx and trachea	1·8	2 0
Testis and penis .	1·5	1·5
	76·3	75·7
All others	23·7	24·3
	100 0	100·0

FEMALES.

Per 100 deaths from malignant disease.

	1897.	1900.
Uterus	23·5	22·5
Breast	15·5	15·8
Stomach	11·3	13·8
Liver	13·2	14·3
Rectum	5·2	5·2
Intestine (ex rectum)	5·2	5·7
Ovary	1·7	1·7
Œsophagus... ...	1·4	1·3
Tongue and mouth...	1·3	0 6
Bladder	0·8	0·9
Jaws	0·6	0·6
Neck	0·6	0·5
	82·3	82·9
All others	17·7	17·1
	100 0	100·0

The general tenour of the results manifested in this table accords with that shown in the preceding one. The proportionate localisation ratios show that there has been no special increase in the "inaccessible" manifestations of the disease; and this is specially noticeable in such organs as the stomach and liver, which comprise the great majority of this form of the disease. Here again, then, Dr. Newsholme's hypothesis is shown to be devoid of solid foundation. Further confutation of this hypothesis comes from the work of Dr. Claud Muirhead, the medical officer of the Scottish Widows' Life Assurance Society,[2] who finds that the cancer death-rate among the assured males was nearly twice as great in 1881–90 as it was in 1861–70. In a society of this kind, the members of which can command the services of highly skilled medical men, it is hardly likely that such a great increase could be due to improved diagnosis and death certification, especially as every death where there was a suspicion of cancer, was carefully investigated. "I think it is evident," says Dr. Muirhead, "that the theory that this large increase was wholly, or even largely, caused by sudden increase of diagnostic skill among the class of medical men who certify causes of death to this Society, is untenable." This contention is fully endorsed by an examination of the localisation ratios in 512 fatal cases in which the exact site of the disease was specified. From this it appears that the deaths from malignant disease of "inaccessible" parts (stomach, liver, &c.) *decreased* by 7·70 per cent. from 1874–80 to 1888–94, and the results thus obtained by comparing the percentages of actual deaths were entirely in accord with those arrived at by comparing the respective death-rates. Thus the reality of the increase of the disease among the members of this society was clearly demonstrated.

[1] THE LANCET, Sept. 16th, 1899, p 765.

[2] The Causes of Death among the Assured in the Scottish Widows' Life Assurance Society, p. 13. Edinburgh, 1902.

Another consideration of similar import is that the increased cancer mortality has been diffused all over the country instead of being limited to certain areas only, so that those localities which formerly had the highest, lowest, and average cancer death rates still preserve their distinction in this respect, although the cancer mortality has everywhere augmented Taking all these facts into consideration there can, then, be no doubt as to the reality of the increase in the cancer mortality

THE DISPROPORTIONATE INCREASE AMONG MEN

The Registrar General's annual reports show that more women die from malignant disease than men and this has been the case ever since these reports were first issued (1837) In the year 1900 this disease was fatal to 16,246 females and to 10,475 males, for females the death-rate was 975 per 1,000,000 living of that sex and for males 672 In other words, 1 in 15 of all men and 1 in 9 of all women 35 years old and upwards eventually died of cancer The cancer mortality among males in that year exceeded the decennial average for the male sex by 16 per cent and among females by 10 per cent Attention is thus drawn to the remarkable fact that the increasing cancer mortality is affecting, and for many years has affected, males to a much greater extent than females. The difference between the sexes in respect to their proclivity to malignant disease has thus been steadily diminishing ever since 1850, as is shown by the following table:—

Table showing the Relative Increase of Malignant Disease among Males and Females

Period	Male cancer death rate	Female cancer death rate	Sex ratio
1851 to 1860	195	434	1 to 2 2
1861 ,, 1870 ..	244	523	1 ,, 2 1
1871 ,, 1880	315	622	1 , 1 9
1881 ,, 1890	430	739	1 1 7
1891 ,, 1900	597	903	1 , 1 5

It thus appears that although there has been a great increase of malignant disease in both sexes during the last half century and although at the present time more women are affected than men yet the malady has augmented much more rapidly among the latter (206 per cent) than among the former (108 per cent) Moreover, it is noticeable that the average age of English women is higher than that of men, so that the death-rates as given above are unduly favourable to the female sex It seems likely if this disproportionate increase of cancer among males be not checked that the disease will soon be as prevalent among men as among women or the comparative proclivity of the sexes in this respect may be reversed, as has already happened in a few countries The greater prevalence of malignant disease among women is entirely due to the frequency with which, in them, the mammæ and uterus are affected, the corresponding structures in males very rarely originating the disease, while in all other localities the male liability is the greater Here it may be noted that the comparative proclivity of women to non malignant tumours and cysts is even more considerable than it is to cancer, and this also arises from the fact that in them the reproductive organs, especially the uterus and ovaries, very frequently originate tumours of this kind, whereas the corresponding male organs are seldom affected Another point worthy of notice in this connexion is that for both sexes the percentage of cancer deaths at ages above 45 is greater than it used to se in the male cancer mor- ssive incidence of the disease

If, now, we ask what is the cause of this disproportionate increase of cancer among men? Newsholme, De Bovis, and others reply. There has been no real increase, but the apparent augmentation is due to improved diagnosis and death certification, owing to the majority of cancers in men being of the "inaccessible" variety, which is difficult to discriminate. As I have in the foregoing remarks fully exposed the fallaciousness of this hypothesis I need not further revert to the matter here

It seems to me probable that this undue incidence of the increasing cancer mortality in men may be ascribed to the fact that of late, *as the result of urbanisation*, the conditions of life for men have come to resemble more closely those for women than heretofore It is undeniable that urbanisation has affected far more profoundly the natural life of men—altering, modifying, and suppressing their ancestral habits, than it has the natural life of women Out of these conditions, which comprise more domesticated surroundings, want of proper exercise and excess of food I believe the present increased cancer mortality has sprung

Clifton, Bristol

PARALYSIS FROM LESION OF THE UPPER PART OF THE BRACHIAL PLEXUS.

BY R T WILLIAMSON, M D, F R C P LOND,
PHYSICIAN TO ANCOATS HOSPITAL AND ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY, MANCHESTER

Two forms of combined paralysis of muscles of the arm from lesions of the nerve roots of the brachial plexus are well known In one form, Erb's paralysis (or the upper arm form), the muscles paralysed are the deltoid, biceps, brachialis anticus, and supinator longus; sometimes also the supinator brevis, the infraspinatus, and the subscapularis In the other well known form, the lower arm form (or Klumpke's paralysis), the muscles paralysed are the small muscles of the hand and the flexors of the fingers and wrist The two cases here recorded are examples of a third form of paralysis of arm muscles in which there is paralysis of all the muscles affected in Erb's paralysis and, in addition, of the triceps and of the extensor muscles of the wrist and fingers The following is a brief abstract of the notes of these cases

CASE 1—A woman, aged 50 years, was knocked down by a bicycle whilst walking in the street In the fall the right shoulder came in contact with the ground About five or ten minutes afterwards she noticed loss of power in the right arm When first seen, four days after the accident, the following muscles were paralysed in the right arm the deltoid, biceps, brachialis anticus, supinator longus, triceps, and extensors of the wrist and fingers. The flexors of the fingers and wrist and the small muscles of the hand were unaffected The pectorals and the trapezius and the latissimus dorsi contracted quite well There was difficulty in rotating the humerus outwards and in writing (especially towards the end of the line) Probably the infraspinatus was also paralysed. Sensation was carefully examined but no change to any form of sensibility could be detected either in the sensory distribution of the fifth, sixth, and seventh cervical nerve roots or in any other part of the arm Electrical examination a few days later showed that the complete reaction of degeneration was absent in the affected muscles The direct application of the weak faradic current to the paralysed muscles ad extensors o ntraction in all, these muscles on the left side To galvanism (direct application to the muscles) all the muscles just mentioned contracted fairly well and the contractions were sharp as in the normal condition—"normal lightning contraction" Also the K C C. was greater than A C C Indirect stimulation of the right deltoid, biceps, and supinator longus through application of the weak faradic current to the combined fifth and sixth cervical nerve roots at Erb's point in the posterior triangle of the neck caused a well-marked contraction of the muscles Galvanic stimulation of the same nerve roots caused contraction of the muscles just mentioned and the K C C was greater than A C C Four weeks after the accident the deltoid and supinator longus were still completely paralysed, on attempting voluntary movements the biceps, triceps, and the extensors of the fingers and wrist contracted slightly but the loss of power in these muscles was still very marked Seven weeks after the accident there was marked improvement In course of time complete recovery occurred There was no swelling or tenderness in the posterior triangle of the neck and there were no other symptoms of lesion of the nervous system Treatment was as follows galvanism (stabile method) was commenced three weeks after the onset of the paralysis There was a daily application of the current for ten minutes

CASE 2—The patient was a boy, aged one year and eight *months One month before attending the hospital the child* was suddenly lifted up by the left arm from the floor. A few minutes afterwards there was pain in the left arm and a few days later it was noticed that the left arm was helpless. On examination the following muscles of the left arm were found to be paralysed completely: the deltoid, biceps, brachialis anticus, supinator longus, triceps, and the extensors of the wrist and fingers. The flexors of the wrist and fingers and the small muscles of the hand were unaffected. There did not appear to be any affection of sensation but owing to the early age of the patient and to his restlessness it was not possible to test sensation very accurately or to take the electrical reactions. Five months later when again examined the paralysis was unaltered. Electrical treatment had been recommended but the mother had brought the child for treatment on one occasion only.

In Erb's paralysis the lesion affects the nerve trunk formed by the union of the fifth and sixth cervical nerve roots (the "upper trunk" of the brachial plexus). In Klumpke's paralysis the lesion affects the eighth cervical and first dorsal nerve roots or the nerve trunk formed by their union ("lower trunk"). In the form of paralysis presented by the two cases just described the same muscles were paralysed as in Erb's paralysis—viz., the deltoid, biceps, brachialis anticus, and supinator longus—but in addition there was paralysis of the triceps and the extensors of the wrist and fingers. By many writers on spinal localisation the triceps and the extensors of the wrist and fingers are stated to be supplied by the seventh cervical nerve root.[1] If this localisation of motor functions be correct the paralysis in the two cases here described could be explained by a lesion affecting either the upper *cord* of the brachial plexus formed by the union of the fifth, sixth, and seventh cervical nerve roots or all those nerve roots separately before their union. The causation of the paralysis is probably similar to that in many cases of Erb's paralysis: compression or laceration of the nerve cord or roots between the clavicle and the posterior part of the first rib, owing to the clavicle being pushed or drawn suddenly upwards and backward at the time when the accident occurred.[2]

Manchester.

A CASE OF ANTERIOR DISLOCATION OF THE SEMILUNAR BONE OF THE WRIST.

BY ERNEST W. HEY GROVES, M.D., B.Sc. LOND.,
ASSISTANT SURGEON TO THE BRISTOL GENERAL HOSPITAL.

CASES in which single bones of the carpus become dislocated are sufficiently rare to justify the publication of the following.

A muscular man, aged 26 years, fell off a ladder whilst gathering walnuts and alighted on the ground, a distance of about 15 feet, striking his right hand and right hip. He thought that he fell on the outstretched palm of the hand. He was sent by Mr. W. Monckton of Portishead to the Bristol General Hospital where I saw him about 20 hours after the accident. The right wrist-joint was swollen and very painful but there was no marked deformity. Both styloid processes were felt in their normal relations. In front of the wrist at the level of the radial styloid process a prominent bony projection could easily be felt. On manipulation no crepitus occurred. Considerable traction could be made on the hand without much pain, showing that there was no injury of the lateral ligaments or fibro-cartilage. Pronation could be carried out but supernation was painful. Flexion of the wrist or fingers was impossible without great pain. Careful measurements from the most prominent points of the styloid processes of the radius and ulnar to the first and fifth metacarpo-phalangeal joint respectively gave about 0·5 centimetre shortening on the affected side. Viewed by the x rays the carpus was seen to be shortened and the proximal row of bones threw an indistinct shadow when viewed from in front or behind. The radius and ulnar were quite normal. When seen from the radial side a projecting shadow of a square bone was cast just in front of the lower end of the radius. Under ether the above points could be made out more distinctly and also the fact that a soft recess occurred just below the line of the wrist-joint on the dorsum and it was evident that the injury consisted in an anterior dislocation of the semilunar bone. Strong traction was made on the hand and the displaced bone was firmly pressed backwards. After one or two ineffectual attempts, the bone slipped back and the hollow on the dorsum of the wrist at once disappeared.

In the rare event of a single carpal bone being dislocated, the dislocation is almost always backwards and affects the os magnum. This is probably due to the fact that the os magnum occupies a central position in the carpus and is wedge-shaped with the base of the wedge on the dorsum. The semilunar is also rather wedge-shaped, but the base of the wedge is towards the palmar aspect and therefore it is that when a violent blow on the wrist crowds together the carpal bones and displaces the semilunar, this bone is forced forwards. Nevertheless, I cannot find any record of the anterior displacement of a single carpal bone and therefore I thought the above case was worthy of record.

Clifton.

A CASE OF SLOUGHING PANCREAS; DEATH FROM SECONDARY HÆMORRHAGE.

BY W. H. BROWN, F.R.C.S. IREL.,
HONORARY SURGEON TO THE LEEDS INFIRMARY.

THE patient, a man, aged 52 years, was quite well up to November last when he had an attack of violent pain at the epigastrium followed by vomiting. A day or two later he became jaundiced and remained so for about six weeks. He had never felt quite well since his first attack of pain and had lost four stones in weight. His present condition was as follows. He looked ill and worn, there was a large fluctuating swelling at the left side of the epigastrium, and he complained of great pain when any pressure was made on the tumour. He also complained of acute pain over the spine of the left scapula. The swelling had not been noticed prior to my seeing him. After consultation with Dr. T. Churton it was decided that an operation was urgently needed.

On the next day under ether I cut down upon the swelling and found it to be a cyst in connexion with the pancreas. About three pints of fluid escaped. The cyst came forward over the upper border of the stomach, not between the stomach and the colon. A large rubber drainage tube was inserted. The fluid was found to contain pancreatic secretion. Dr. P. J. Cammidge's tests were made for me by Dr. O. C. Gruner and suggested malignant disease. The urine tested *before* the operation contained neither sugar nor albumin. The patient made good progress for ten days, the pain all went, and about 12 ounces of fluid were drained off each day. On the tenth day the tube came out and could not be replaced, the temperature ran up to 105° F., and a hæmorrhage took place which exhausted the patient rapidly. Transfusion of saline solution failed to revive him and he sank within 12 hours of the hæmorrhage. I was enabled to obtain the parts immediately concerned but not to make a post-mortem examination as usually understood.

On introducing the hand the viscera in the upper zone of the abdomen were matted together and adherent to the abdominal wall. There was an opening about three-quarters of an inch in diameter through the lesser omentum and the lesser sac was occupied by non-offensive, dirty-brown material, together with recent blood clot. There was a large quantity of free blood in the peritoneal cavity. The stomach, duodenum, and pancreas were removed *en masse* for further examination. On turning the attention to the pancreas that organ was found to be replaced for the most part by soft, black, necrotic-looking tissue. There was no healthy pancreatic tissue left. The extreme tail of the organ was least affected and the nature of the tissue here could be quickly recognised, but even this was considerably decayed. The lesser sac was occupied by soft brown débris, evidently of pancreatic origin. On the great omentum and on the mesentery were several light yellow and white areas of fat necrosis The spleen was very large and its substance was soft, otherwise it was normal The liver and bile passages were normal, there were no gall stones

[2] [illegible] of Paralysis of Muscles of the Upper Extremity of Peripheral Origin, with special Reference to their Causation, THE LANCET, Dec. 11th, 1897, p. 1522.

This is the third case of pancreatic cyst upon which I have operated the former two were traumatic and recovered The points of importance appear to be the obscure origin of the disease the rapid loss of flesh that took place without the presence of malignant disease, and the intensity of the pain over the shoulder which entirely disappeared when the patient came round from ether It is an interesting fact that the tests of Dr Cammidge carried out by an expert resulted in a refutation of the statement that with certain reaction new growth will be found I have thrice before met with cases in which profuse hæmorrhage occurred without obvious cause and in each case there was evidence of inflammatory changes in the pancreas

WESTMINSTER HOSPITAL

A CASE OF ULCERATIVE COLITIS

(Under the care of Dr W MURRELL)

A MAN, aged 64 years, was admitted into Westminster Hospital on May 28th suffering from ulcerative colitis He was born in England his father was an Englishman and his mother a native of Calcutta When a few months old he was taken to India and remained there until the age of 36 years when he returned home Whilst in India his health was perfect and he had neither diarrhœa nor dysentery About ten years ago he developed a chronic and intermittent diarrhœa which during the past 12 months had been accentuated, the bowels as a rule acting four times in the day and five times at night He had attended as an out patient for nearly a year but the diarrhœa continued with unabated severity in spite of much treatment He had been steadily
months There were

On admission and fo
ture was elevated, varying from 99 4° to 101 8° F There were usually from five to seven motions in the 24 hours, the stools being fluid fairly copious slimy free from blood, and not offensive There was no vomiting There was hyperæsthesia on deep palpation all over the abdomen The tongue was clean and moist

The patient was dieted and given acetate of lead and other astringents but without benefit and his general condition was unsatisfactory From June 5th to 9th inclusive he had 23 motions On the 10th after a preliminary enema of boric acid eight grains to the pint he was given by means of an irrigation tube of small diameter a rectal injection of a 1 per cent aqueous solution of argyrol at a temperature of 80° When about five pints had been introduced, the patient being in the knee and elbow position attention was called to the fact that a claret-coloured odourless fluid was pouring out of his mouth, a fluid identical in colour and appearance with that in process of injection into the rectum The time from the commencement of the injection was four minutes There was some nausea but no retching or vomiting and the fluid as it flowed from the mouth was received into a clean white porring
A suggestion being made that it was altered blood it
examined both microscopically and by the usual tests
no blood was present It was examined for bile and ag
with a negative result The patient had taken nothing in the way of food but some tea early in the morning and subsequently a little milk and bread and butter The specimen was then sent to Dr Wilson Hake at the Westminster Hospital Medical School who after complete analysis, reported that it was a solution of silver not differing apparently from a 1 per cent argyrol solution with which it was compared

The patient seemed none the worse for the injection and had a fairly good dinner On the following day he had only three motions and on June 12th the same number The temperature was normal on the 11th but on the 12th it rose to 102 4° falling again in a few hours to normal From this time there was no return of the diarrhœa the bowels never being opened more than once a day As a matter of precaution the injection was repeated on the 14th and 16th but there was no repetition of the regurgitation of fluid from the mouth In a few days the patient was able to take meat potatoes and green vegetables, he rapidly regained weight and on July 6th was discharged well

Remarks by Dr MURRELL —The foregoing case illustrates (1) the curative effect of an injection of argyrol into the bowel in a case of ulcerative colitis, and (2) the fact that a fluid introduced into the rectum may be discharged unaltered by the mouth This case should be read in conjunction with the five cases of ulcerative colitis published in THE LANCET of March 12th, 1904, four of which terminated fatally It was there stated that with the exception of injections of silver almost every drug or combination of drugs had been tried and that they all failed It would be unwise to jump at a conclusion from the experience of a single case but it looks as if argyrol had solved the difficulty This salt is a chemical combination of silver with synthetic vitellin and contains 30 per cent of silver The evacuation of a substance injected into the rectum in so short a period as four minutes is noteworthy There is no doubt about the fact for the fluid was seen running out of the mouth and Dr Wilson Hake's careful analysis is conclusive It may be suggested that there was a short circuit between the rectum and the stomach but there was nothing pointing to the existence of so abnormal a condition The occasional *vomiting of enemata* by hysterical and other patients is not unknown and many cases are recorded

Many years ago Nothnagel reported as the result of a series of experiments that anti peristalsis never occurred in the normal uninjured intestine if
were brought to bear on it The
the injection into the rectum of
carmine post mortem examination showing whether they had been carried higher by any movement of the intestine itself The best results were obtained with from three to five cubic centimetres of a strong solution of chloride of sodium, but the staining never reached farther than the cæcum Angeraut, in a thesis published in Paris in 1894, affirmed as the result of experimental investigations that the ileo cæcal valve did not always present the adequacy attributed to it by anatomists and that it might be permeated by fluids introduced into the rectum Coutani has recorded two cases in which after injections of large quantities of olive oil into the rectum for the relief of constipation the patients were seized with eructations and vomiting the vomited matter containing oil Jaccoud mentions the case of a hysterical young woman who from time to time vomited motions which were formed cylindrical brown in colour and of characteristic odour Fully realising the deception often practised by such patients every possible precaution was taken but the phenomenon continued Ten days later the patient contracted enteric fever, dying in the third week but at the necropsy no anatomical peculiarity was detected there being nothing observable but the characteristic lesions of the disease Briguet reports a case in which an enema of coffee was vomited a quarter of an hour after its administration Experimentally an injection was given of a fluid coloured blue with tincture of litmus and in 12 minutes it was rejected by the mouth having been turned red by the acid of the gastric juice In a similar manner a saline injection was evacuated by the mouth and gave the usual reaction with nitrate of silver He mentions a case in which an injection of 150 grammes of almond emulsion containing ten minims of tincture of opium, was vomited in half an hour, the patient distinctly recognising the taste of the laudanum
imes rejected by the mouth
a girl, aged 12 years, who
introduced into the rectum
Pater noster et un *Ave Maria*
A second suppository secured by a thread was then introduced, but the reverse peristalsis was sufficiently strong to break the cord and the suppository was vomited with the fragments of thread attached A third suppository was

tried, secured by four strong ligatures, but the result was the same. Several similar cases are recorded in Dr. A. P. Gros's "Traitement de certaines Maladies de l'Estomac."

SUSSEX COUNTY HOSPITAL.

A CASE OF CEREBRAL HÆMORRHAGE WITH ARRESTED RESPIRATION FOR 18½ HOURS.

(Under the care of Dr. E. MACKEY.)

FOR the notes of the case we are indebted to Dr. T. Barrett Heggs, house physician.

A man, aged 23 years, was admitted into Sussex County Hospital under the care of Dr. Mackey on July 20th, 1903, with violent headache. The family history was *nil.* There was a strong hereditary tendency of tubercle in his uncles, aunts, and cousins, but in no nearer relative. He denied having had syphilis. He had had pneumonia in 1899. He dated his present illness back to October, 1901. When in the mounted infantry in South Africa he was thrown from a horse at Spitzkop, was concussed, and received a scalp wound. No symptoms followed till March, 1903 (18 months after the accident), when frontal and occipital headache came on each day and often prevented sleep at night. He was faint, sick, and giddy, and often vomited with headache. For two months he had been unsteady in walking and his knees gave way.

On admission the pulse was 80 and the respirations were 20. The patient's appearance was normal. There was no tenderness or depression in the skull. His mental capacity was rather subnormal and he was slow of speech. The headache generally came on in the early morning, sometimes passing from the forehead across the vertex to the occiput; at others it was constant in the frontal and occipital regions. His gait was ataxic and reeling and he fell to either side but more to the right. Romberg's sign was positive even with the eyes open. The pupils were dilated equally, reacting to light and to accommodation. There was no paresis or nystagmus. There was a small patch on the inner margin of the right optic disc, probably congenital in origin. No sign of optic neuritis was present (Mr. W. W. Griffin). The organic reflexes were normal. The knee-jerks were slightly exaggerated on both sides. There was no patellar clonus. Ankle clonus was present on both sides, more sometimes in one than the other. The plantar reflex was present, sensation was normal, power was good, and there was no Babinski reflex. Coördination in the arms was slightly imperfect and was worse in the left arm, but power was good and sensation was normal. The wrist and triceps jerks were normal. The pulse was small, regular in force and rhythm, and normal in tension. There was an occasional reduplicated first sound of the heart, otherwise that organ was normal. The symptoms improved much for a time, but from August 26th the headache became gradually worse, generally appearing between 3 and 5 A.M. and often followed within an hour or so by vomiting. The vomiting sometimes followed walking about more than usual. The fundi still showed absence of optic neuritis. The temperature was continually subnormal (from 97·4° to 98·2° F.). The treatment internally was iodine—first as the syrup of hydriodic acid and later as iodide of potassium in 20-grain doses three times a day, also antipyrin, bromide, and cannabis indica as required. During the night of the 26th the headache was very bad. He vomited at 3.30 A.M. The headache, relieved by a powder for a time, recurred later in the morning and sinapisms were applied to the nape of the neck. At 1.40 P.M. Dr. Mackey was called to see the patient. He found him lying with eyes open and fixed, equally dilated pupils and not reacting to light, and insensitive corneæ. The face was grey and cyanosed and there was slight twitching of the jaw but no other movement. There was no attempt at respiration made (no moisture was deposited on a mirror). The pulse was irregular but otherwise very fair. The patient was quite warm. All the muscles were quite flaccid. Artificial respiration was begun and sufficient respiration could be maintained by rhythmical compression of the chest. In a short time the patient regained a good colour and the pulse improved. Artificial respiration was discontinued for 15 minutes and the patient became cyanosed and the pulse irregular. On resuming artificial respiration the colour and pulse improved. Oxygen was tried with no effect. Ether and strychnine were injected. Amyl nitrite was given but still no attempt at respiration was made. The faradic current applied with a pole on the nape of the neck and the other over the brachial plexus produced contraction of the extraordinary muscles of respiration and it was possible to keep up artificial respiration by this contraction and as the muscles failed to respond compression of the chest was resumed. Still the pulse was very fair but at times irregular.

A surgical consultation discountenanced trephining, since absence of stertor was taken to indicate absence of brain pressure. Lumbar puncture was performed at 6.15 P.M. and four drachms of clear cerebro-spinal fluid were drawn off (bacteriological examination failed to find any abnormality in it), after which the pulse improved but the general condition remained the same. An attempt to pass a catheter caused erection of the penis. Nutrient enemata were given every four hours. Artificial respiration was continued all night. Ether and strychnine were given hypodermically as required more and more frequently. Mercurial inunction was carried out. 12 ounces of saline solution were injected per rectum at 9.20 P.M.; this was retained; when repeated at 6.30 A.M. it was returned. The pulse ceased at 8.15 A.M. on August 28th, 18½ hours after the respiration ceased.

Necropsy.—To the naked eye there was no sign of tubercle in the body. The organs were normal, as were also the cranial bones and the spine. The cerebral membranes, sinuses, and arteries were normal. There was no meningitis. No tubercles were present on the meninges There was an excess of cerebro-spinal fluid. The ventricles were not over-distended. The medulla and upper cord were normal. The lower cord was not examined. At the outer side and upper aspect of the right hemisphere of the cerebellum an old blood-clot half an inch in diameter was found lying just under the surface; also a more recent small hæmorrhage in the left lobe of the pons. A section of this portion on microscopical examination showed thrombosis of some of the larger vessels with commencing organisation of the clot. The surrounding cerebral substance was degenerated. The most striking features of the section were the periarteritis and the enormous polynuclear giant cells in contact with many of the capillary vessels. (Query, traumatic, specific, or tuberculosis? Either might be followed by thrombosis.)

The second more recent hæmorrhage in the pons was no doubt the cause of the peculiar symptoms and of death. Was the primary hæmorrhage in the cerebellum produced in South Africa 18 months before the onset of symptoms? This seems improbable.

Reviews and Notices of Books.

Introduction à l'Etude Clinique et à la Pratique des Accouchements: Anatomie, Présentations et Positions, Mécanisme, Toucher, Manœuvres, Extraction du Siège, Version, Forceps. By Professor L.-H. FARABEUF and Dr. HENRI VARNIER. Preface by Professor A. PINARD. Illustrations by L.-H. FARABEUF, being with necessary repetitions 362 figures. New edition revised and corrected by Professor L.-H. FARABEUF. Paris: G. Steinheil. Price 15 francs.

THE appearance of a second edition of this well-known work will be welcomed by all obstetricians. The death of Professor Varnier has left the task of revision to Professor Farabeuf. He has embodied all the most recent researches and has rewritten in great part some of the chapters, more especially the one dealing with the application of the forceps to the head lying above the pelvic brim. The increase in the number of operations of symphysiotomy and of Cæsarean section performed in France has caused some alteration in the treatment advocated in this chapter for such cases. The book contains an immense amount of information on all the problems connected with the progress of natural labour. The anatomy of the pelvis and of the fœtus, more especially of its head, is very fully discussed, this is followed by a description of the mechanism of labour in all the different presentations, and then the method of carrying out vaginal examinations and the diagnosis of the various presentations are given in great detail The rest of the work is concerned with the operative delivery of the breech, the treatment of shoulder presentation by version, and the application of the forceps The descriptions are rendered the more valuable in that they are illustrated and confirmed by the numerous researches which the authors have carried out in these various subjects These experiments have been conducted in the most natural manner possible, as they have been practised on the "natural mannequin"—that is to say, on cadavers, mainly those of women dying from eclampsia during the course of, or before, the onset of labour and in whom the natural passages were still in good condition and dilatable These experimental studies have been controlled by laboratory researches on frozen sections of the bodies of women who died during pregnancy or during labour and by clinical observations in the clinique of Professor Pinard The outcome of the authors' studies—viz, this volume—is of the highest possible merit and forms a most valuable memorial of the late Professor Varnier, to whom a great deal of the credit is due The book is one of the most important modern contributions to obstetric literature and will be welcomed in its revised form by all those who are engaged in the study of this branch of medicine. The figures which form so marked a feature of the book, and many of which have found their way into numerous text-books of midwifery, are most admirably drawn and reproduced

The Pocket Companion to the British Pharmacopœia By PETER WYATT SQUIRE London J and A Churchill 1904 Pp 766

Squire's "Companion to the British Pharmacopœia" has long been known and valued by the members of the medical profession and by all interested in recent advances in pharmacy The present volume is constructed on the same lines and its smaller size is intended to render it more serviceable, it must, however, be admitted that the name of "Pocket Companion" is rather a misnomer, for few medical men with any regard for the fit of their garments would care to find room for this book in addition to the other necessary articles they have to carry about with them It may be a "handy manual" but it is not a pocket companion The author states that he desires to afford information on such matters as are commonly arising in the ordinary course of prescribing and dispensing, while giving notes on improved pharmaceutical processes and criticisms on the official tests which involve a considerable amount of experimental work

The adaptation of material to the smaller setting has been effected with great discrimination The author has retained just those features for which the "Companion" was most frequently consulted by medical men and has exerted judicious compression in many directions Although generally arranged in alphabetical order the divergences from this plan are sufficiently numerous to render indispensable frequent reference to the index and it may at once be stated that the index appears to be very complete By the use of small type for many new remedies, which are comparatively little used, much space has been economised to be devoted to more important amplifications of "Prescribing Notes" It is, perhaps, a sign of the times that the 50 spas in Britain of the larger "Companion" are reduced to nine in the smaller book and that we are spared the long analytical tables relating to the foreign spas. About 30 pages of the "Companion" which dealt with articles employed in chemical testing have also been deleted with advantage, these are of necessity included in the British Pharmacopœia but they were not required in the "Companion" and we are glad not to find them in the "Pocket Companion"

We have tested this volume in many places and we have not noticed any serious omissions in the attempt to include in a small space reference to all noteworthy therapeutic developments The only exceptions are that the author refrains in most instances from ascribing any medicinal properties to many of the drugs included in the Indian and Colonial Addendum to the British Pharmacopœia Dr. R. Tanner Hewlett has rewritten a short section on Therapeutic Agents of Microbial Origin The book concludes with a therapeutical classification of remedies and with a list of remedies employed in special ailments which betray the difficulty inseparable from the attempt to find hints of value under the name of a disease or symptom Thus in seven lines remedies for flatulence are included and the same space is allotted to remedies for typhoid fever, with no indication of the circumstances in which any one of them may be required The author is to be congratulated upon the thoroughly practical value of all that relates to dispensing and prescribing and we must not cavil if on matters of treatment the information is not up to the level of the branch of medicine in which he has personal experience

---

Membranous Catarrh of the Intestines By Professor Dr CARL VON NOORDEN, Physician-in-Chief to the City Hospital, Frankfort on-the-Main With the collaboration of Dr CARL DAPPER Bristol John Wright and Co 1903 Pp 64 Price 2*s* 6*d*

THIS volume constitutes Part III of several "Clinical Treatises on the Pathology and Therapy of Disorders of Metabolism and Nutrition" written by Professor von Noorden A very good account is given of the clinical characters of membranous catarrh of the intestines, sometimes called "colica mucosa" The two cardinal signs of the disease are evacuation of mucus and recurring attacks of pain The authors point out that the excreted mucus may assume different types, that it may either be loose and glairy, or that it may be more solid, drier, and formed of strands that are tightly interlaced to form reticulated structures These two types, however, represent extremes and between the two many intermediary transitions are noticed Professor von Noorden considers that the disease is due to the existence of some morbid nervous reflex process brought about by the irritation of the intestinal mucosa by dry hard scybala and upon this assumption the treatment of the malady is founded, The portion of the work devoted to treatment will be found very interesting and as the condition not infrequently proves rebellious to ordinary measures much may be learned from a study of these pages

Professor von Noorden and Dr Dapper divide the treatment into symptomatic and "causal" The object of the former is to suppress the attack as soon and as completely as possible This is necessary in order to relieve the pain and the distress of the patient and so to prevent the deleterious consequences that may follow both in regard to the general nutrition of the sufferer and the whole nervous system To this end rest in bed is indicated and the authors unequivocably advise the administration of narcotics, although some physicians oppose this course Morphine or opium may be given either by hypodermic injection or in the form of suppositories Enemata of oil and water are also recommended The "causal treatment" is described at length. Any treatment of diseases of the digestive tract must in the first place be dietetic and after considerable experience Professor von Noorden is emphatic in recommending a coarse laxative diet consisting of bread containing a large proportion of husks, as great a variety as possible of leguminous plants including the husks, and fruit with small seeds and thick skins, besides large quantities of fat, in particular of butter and bacon. Massage of the large intestine, especially of the sigmoid flexure, is also advised. It is claimed that treatment on the above lines will speedily bring about a complete cure. We have merely given the general outline of the course to be pursued and can recommend our readers to refer to the original work for the details of the daily routine which is necessary in order to bring about the desired effect.

International Clinics. Edited by A. O. J. Kelly, A.M., M.D., Philadelphia, U.S.A. Vol. III. (1903) and Vol. IV. (1904). Thirteenth series. London: J. B. Lippincott Company. Vol. III., pp. 305, price 10*s.* 6*d.*; Vol. IV., pp. 321.

MANY interesting papers are contained in the third volume (thirteenth series) of this well-known publication. There are several good communications on diseases of the gall-bladder and gall-ducts—namely, Some Medical Aspects of the Diseases of the Gall-bladder and Gall-ducts, by Dr. J. H. Musser; the Causation, Symptoms, and Diagnosis of Gall-stones, by Dr. R. D. Rudolph; the Diagnosis and Medical Treatment of Cholelithiasis and Cholecystitis, by Dr. C. G. Stockton; Biliary Cirrhosis of the Liver, with and without Cholelithiasis, by Dr. F. Parkes Weber; the Value of, and Indications for, Surgical Intervention in Cholelithiasis, by Dr. F. Lejars; and the Surgical and Post-operative Treatment of Chronic Gall-stone Disease, by Dr. J. B. Deaver. These form an interesting group of papers dealing with morbid conditions of frequent occurrence the diagnosis and treatment of which have of late years received considerable attention. Dr. Stockton remarks on the occurrence of pericholecystitis in connexion with cholelithiasis, which gives rise to continuous pain and some constitutional disturbance. There is then a localised peritonitis which may extend sufficiently to produce the gravest results, even causing perforation. While in some cases, as the result of ulceration, a passage may be formed between the gall-bladder and the intestine, thus leading to drainage of the gall-bladder, possibly the escape of calculi, and even ultimate cure of the case, it too often happens that a perforation into the peritoneal cavity results from the process, following which a rapid septic peritonitis is to be expected. Another interesting article in this volume is that on Malarial Infections and their Parasitology, Symptomatology, Diagnosis, and Treatment, by Dr. C. F. Craig. The author's remarks on the "mosquito cycle" of the malarial parasites are particularly worthy of note.

Vol. IV. contains many interesting communications on important subjects. Dr. J. Tyson writes on the Clinical Features and Treatment of Ulcer of the Stomach. He rightly draws attention to the operative treatment of this affection. Experience is accumulating showing the good results that have been obtained in those cases which have defied treatment by the ordinary means. Dr. Tyson refers mainly to those instances which have been characterised by the occurrence of severe hæmatemesis. There is, however, another type in which the patient's life is rendered wretched owing to the constant pain and vomiting induced by taking food; in these cases operation has been followed by complete or very great relief. Attention may be drawn to an article by Dr. James Burnett on Angioneurotic Œdema. This is a condition which has not been very generally recognised; it may be defined as a circumscribed swelling associated with changes of sensation in the part affected and occasioned by a vaso-motor neurosis. The site of the swelling may be almost anywhere but the commonest areas involved are the eyelids, lips, cheeks, throat, hands, and feet. Dr. Burnett believes that the source of the affection lies in the medulla. The vaso-motor centre is readily influenced reflexly by sensory nerves but it can act quite automatically —that is, without the intervention of external stimuli. He recognises three clinical varieties: the traumatic, the neurotic, and those cases associated with the menopause. For clinical purposes this classification may be conveniently accepted. The treatment of angioneurotic œdema is similar to that of mild cases of neurasthenia.

Amongst the communications on surgical subjects is one by Mr. W. H. Battle and Mr. E. M. Corner on the Differential Diagnosis of Acute Abdominal Conditions which require Surgical Treatment. Appendicitis naturally at once presents itself to the practitioner's mind when an acute abdominal case is seen. The differential diagnosis in such instances may be most difficult, yet on the diagnosis and line of treatment may depend the patient's life. Mr. Battle and Mr. Corner deal with the subject of diagnosis of acute abdominal conditions in a most able manner and their observations are worthy of careful study. The volume concludes with an admirable *résumé* on the Present State of our Knowledge of Immunity by Dr. J. McFarland.

Text-book of Diseases of the Eye for Students and Practitioners of Medicine. By HOWARD F. HANSELL, A.M., M.D., Professor of Diseases of the Eye, Jefferson Medical College, Philadelphia; and WILLIAM H. SWEET, M.D., Demonstrator of Ophthalmology, Jefferson Medical College. With chapters by CHRISTIAN R. HOLMES, M.D., CASEY A. WOOD, M.D., and WENDELL REBER. With 256 illustrations, including coloured plates. London: Rebman, Limited. 1903. Pp. 532. Price 17*s.* net.

THIS text-book contains a very good *résumé* of the present state of ophthalmological knowledge and is well adapted to the purpose for which it was designed. It is essentially practical and hence but scanty space is devoted to optics. There is, however, sufficient to enable brief explanations accompanied by diagrams to be given of the nature of prisms and of the forms and proportions of concave, convex, and cylindrical glasses, of mirrors, of the formation of the image in the ophthalmoscope, in the ophthalmometer, and in retinoscopy, as well as of the adaptation of lenses for the correction of errors of refraction. The style is clear and if the contents of the work are thoroughly mastered neither the student nor the practitioner need be apprehensive of the correctness of his diagnosis or of the propriety of the treatment which he intends to adopt. In the section on Phlyctenular Keratitis we notice that the authors recommend, and in this we are in full accordance with them, that the use of sweetmeats and pastry should be interdicted.

A good section is devoted to the subject of Foreign Bodies in the Eyeball, wherein it is shown that their presence and nature can be to some extent determined by a consideration of the circumstances in which the injury was inflicted. Another symptom to be noted is the presence of "siderosis," or the rusty-brown discolouration of the iris which is likely to follow persistent retention of any foreign body in the eye. The use of the ophthalmoscope and especially the employment of the Roentgen rays, by means of which a shadow can be obtained of a fragment of shot, glass, stone, or coal, and of the sideroscope (not "siderscope" as given both in the text and index) are also considered; and notice is called to the pain caused by the approximation of a strong magnet. Good woodcuts are given showing the old-fashioned Hirschberg magnet, the medium-sized magnet of Dr. Sweet, one of the authors of this treatise, and the giant magnet of Haab, and directions are given in regard to the mode in which magnets should be used. There is an interesting and valuable section on the Economic Value of Vision—a subject which has hitherto not received sufficient attention.

The chapters on the Diseases of the Lacrymal Apparatus, Orbit, and Cavities accessory to the Orbit, by Dr. Christian R. Holmes of Cincinnati; on Ocular Symptoms in General

Disease, by Dr. Casey A. Wood of Chicago; and on the Pupil in Health and Disease, by Dr. Wendell Reber of Philadelphia, are important and valuable additions to the work. Dr. Holmes recommends the gradual dilatation of the ducts in cases of lacrymal obstruction, increasing the size until the largest probes are passed, which, although good authorities may be cited for the practice, we are inclined to regard as rarely advisable, as a matter of fact, epiphora often occurs even when the larger probes can be easily passed.

In speaking of the operations for cataract the authors are cautious in their statements but appear to prefer the operation of extraction with iridectomy. They remark, however, that "the simple is the ideal method in selected cases, its great advantage consisting in the preservation of a round pupil. The greater difficulty in expressing the lens and in freeing the anterior chamber of particles of retained cortical material is not regarded as an argument against the operation. The most serious objection to simple extraction is the frequency of prolapse of the iris. Moreover, operations for after-cataract are more frequently required. The disadvantages of the combined operation are the mutilation of the iris, hæmorrhage into the anterior chamber, and subsequent disturbance of vision by the coloboma." They consider the combined operation to be undertaken preferably in nervous patients; in all complicated cataracts; in cases where the iris reacts sluggishly or where the anterior chamber is shallow; in immature cataract, and in eyes the subject of chronic inflammation. Amongst the dangers of the operation not mentioned by the authors is the failure to recognise that the point of the knife has not penetrated the whole thickness of the cornea but is travelling between the layers. We have seen this occur on several occasions in inexperienced hands with fatal results to vision. The authors might with advantage have sounded a note of warning to young practitioners against undertaking at too early a period an operation for the division or removal of a secondary cataract. Cortical substance undergoes absorption in the course of a year or two with steady improvement in vision and if the needle is too freely used the vitreous, bulging forward, is apt to block the irido-corneal angle and to induce an attack of glaucoma, for which instant attention and probably operation are required. Needling for secondary cataract should not be undertaken without due consideration.

A feature of the book is the excellence of the illustrations which we have not seen surpassed and which are set off to the best advantage by the quality of the paper on which they are printed. One or two of them are coloured but there are several in which the introduction of colour would be a distinct improvement. For example, in the illustration of interstitial keratitis the shading required to represent the fine pericorneal branches of the anterior ciliary arteries, though quite correctly placed, gives the impression of a marked chemosis, the cornea appearing at the bottom of a pit, a condition which in that affection does not occur. Were the ciliary circumcorneal zone coloured this aspect of a depressed cornea would be removed. The drawing representing the arteries and veins surrounding the eye would also be much improved by tinting these vessels red and blue respectively and coloured drawings of some of the diseases of the fundus would add to the beauty of the work and at the same time render it more instructive to the student. The illustrations of the operations for the extraction of cataract, for pterygium, for tenotomy, for iridectomy, for entropion and ectropion, for tarsorrhaphy, and those showing various diseases as glioma, carcinoma, sarcoma, and lacrymal affections, are all very creditably executed and will prove serviceable to the practitioner who is called upon to operate. We have much pleasure in recommending the volume to our readers.

LIBRARY TABLE.

A Manual of the Practice of Medicine. By A. A. STEVENS, A.M., M.D., Professor of Pathology in the Woman's Medical College of Pennsylvania; Lecturer on Physical Diagnosis in the University of Pennsylvania; Physician to the Episcopal Hospital and to St. Agnes' Hospital. Sixth edition, revised and enlarged. Illustrated. London, Philadelphia, and New York: W. B. Saunders and Co. 1903. Pp. 556. Price 10*s*. 6*d*.—This manual is intended especially for students and as it has reached a sixth edition it has evidently been duly appreciated. For purposes of examination, however, we cannot recommend it to English students, but to supplement study in the wards and out-patient rooms—in other words, as a guide to purely clinical work—it will be found useful. The remarks on physical examination will considerably aid the student in the early days of his study of practical medicine. By reference to a book of this nature many hints may be obtained which will prove of value in intimating the phenomena which may occur in various diseases and how they should be interpreted. A student may be able to hear certain sounds with the stethoscope but he requires instruction as to the correct deductions to be made from them. Throughout the book the remarks dealing with symptoms and physical examination are quite satisfactory but those concerning pathology are too condensed to be of real value. The subject of differential diagnosis also is considered very briefly. This is especially so in the section on diseases of the nervous system. The directions as to treatment are necessarily condensed but the author has succeeded in giving a large amount of useful information in a small space. In this edition the entire section on diseases of the digestive system has been rewritten and will now be found full and accurate.

Olive Latham By E. L VOYNICH. London: William Heinemann. 1904. Pp. 286. Price 6*s*.—This is a very painful and exceedingly clever book. Olive Latham is the daughter of a curiously mixed parentage, for her father was a scholar and an enthusiast with a passion for the education of the masses, while the mother was a woman of the eminently respectable middle-class English type who presented her daughter with the "Poems of Frances Ridley Havergal" when she went away to become a probationer in a hospital. When later she came home as a nurse she was somewhat of a trial to her father, being a little like the lady of whom it was said that she was "icily regular, faultily faultless." When her father had "given her in the shy, half reluctant way of a man naturally reserved and long used to silence some small hint of his secret grief" she did not wound him by any tactlessness; she listened to him with grave attention, but next morning when he came down to breakfast he found some small pepsin tablets laid beside his plate. But Olive Latham had at the same time infinite potentialities for romance. She had become engaged to Vladimir Damarov, a Russian revolutionist, and on the receipt of an urgent telegram from Karol Slavinski, a Polish friend of his, she starts at once for Russia to nurse him. The Russian section of the book, which is saturated with the horror of despair, is the most effective part of a remarkable work. There is no fine writing about it and the pity of it is that it reads like absolute truth. Small wonder that Olive's nerves broke down after Vladimir's death or that on coming home she should have suffered from that horror of black darkness which many know so well but which we have never seen so well described. Mrs. Voynich's psychology is sound and learned without being priggish, therefore it is convincing, while she deserves great praise for the care which she has taken to get her medical details correct, especially as she afflicts Karol Slavinski with disseminated sclerosis. The book is not a cheerful one but it is well worth reading.

THE

BRITISH MEDICAL ASSOCIATION.

MEETING AT OXFORD.

THE SECTIONS.

MEDICINE.

FRIDAY, JULY 29TH.

Dr. J. MACKENZIE (Burnley) opened the meeting by reading a paper on

The Maternal Heart in Pregnancy.

The results of an inquiry into the changes in the circulation of healthy pregnant women were given. These pointed to inefficiency in the work of the heart, particularly to engorgement of the right side. This was extremely marked in mitral stenosis, and an analysis of certain symptoms was given to illustrate the danger of pregnancy in these cases. The murmurs of mitral stenosis were dealt with and it was shown that the lesion was progressive; when the presystolic murmur disappeared and only a diastolic murmur was left the auricle was paralysed and the cardiac rhythm became irregular. Tracings of the apex beat and jugular veins were shown to prove these statements. Dr. Mackenzie considered that pregnancy should be forbidden when there were marked signs of failure of compensation, and even when with fair compensation the pulse was irregular, or when only a diastolic murmur was present at the apex. If pregnancy had already begun it was justifiable to interfere in such conditions. Pregnancy might be permitted with a presystolic murmur and a normal apex beat within the nipple line. The onset of œdema of the lungs was the most important sign to watch for during pregnancy. The paper was illustrated by many tracings of the radial pulse, the apex beat, auricular contraction, and jugular wave in the conditions described.

Dr. H. O. NICHOLSON (Edinburgh) read a paper on

The Management of Cases of Pregnancy complicated by Heart Disease,

in which he considered the following points: (1) the blood pressure during normal pregnancy; (2) the conditions leading to hypertrophy of the heart during pregnancy; and (3) the state of tone of the arteries and arterioles, as observed (*a*) in primiparæ and (*b*) in multiparæ, during normal pregnancy and when the pregnancy was complicated by disease of the heart. During pregnancy a toxin of unknown nature led to increased peripheral resistance which might become great enough to cause anuria and eclampsia. With regard to the treatment of dropsy occurring towards the end of pregnancy small doses of mercury two or three times a week gave better results than any vegetable aperient. Vasodilators were of great value where the embarrassed heart threatened failure; and two cases were quoted where 15 grains of thyroid extract given daily relieved the cardiac engorgement and aided diuresis. If alarming symptoms occurred from distension of the right heart towards the end of labour amyl nitrite was of value.

Dr. G. A. GIBSON (Edinburgh) read a paper on

Bradycardia,

illustrated by lantern slides. The so-called false bradycardia, or slow pulse unaccompanied by slowness of the heart, called for no consideration. True bradycardia or slowness of the heart beat fell under several categories: (1) cases in which the whole heart was involved, owing to the influence of the vagus; (2) cases in which the conductivity of the cardiac impulse was impaired, only a few of the auricular contractions being conducted to the ventricle; and (3) cases in which the ventricle took on an independent rhythm, pulsating without any preceding contractions of the auricle. Tracings were exhibited to the meeting, taken from a case in which the radial pulse had varied from 26 to 32 per minute. By taking tracings at the same time from the jugular vein and from the radial artery it was seen that to one beat of the radial there were three or four beats of the auricle. Tracings of the same case taken synchronously from the apex beat and the jugular vein showed that only one of three or four auricular contractions was conducted to the ventricle. Tracings from other cases showed imperfect ventricular pulsations which were too weak to cause a peripheral pulse wave. In cases of recurrent bradycardia epileptiform attacks were frequent sequelæ and were first described by Adams of Dublin. As regarded the cause of bradycardia Dr. Gibson had already expressed the opinion that with imperfect circulation in the brain any undue exertion of the brain tissues might lead to recurrent bradycardia. In response to a request from Dr. T. D. ACLAND (London) that he should give his experience in the treatment of bradycardia, Dr. Gibson said that he had never found atropin to be of any use, but digitalis, strophanthus, and other members of the digitalis group had in his hands yielded more or less success. He believed that they acted by improving the nutrition of the cardiac muscle. It was all-important that the vessels of the abdomen and its viscera should not be dilated and he believed that for the attainment of this object a modified course of Ling's Swedish gymnastics was of greater use than the Nauheim method of treatment.

Dr. W. J. TYSON (Folkestone) stated that in his experience bradycardia was more common in old age and in women and that atropin was of value in its treatment.

Serum Treatment of Disease.

Dr. E. W. GOODALL (London) opened a discussion on the Present State of Serum Therapeutics, with a brief review of the origin of serum therapeutics ten years previously and their subsequent rapid development. He stated his intention of referring only to antitoxic sera proper—i.e., the blood serum of animals immunised against certain diseases, usually bacterial. There were two kinds of sera now in use: (1) antitoxic, neutralising the toxic products of a micro-organism; and (2) antimicrobic, destroying the organism itself or inhibiting its action. There were two [illegible] of diseases: (1) the intoxications [illegible] as an example), and (2) the infections (of which plague was an example). Antitoxic serum was prepared by immunising animals with toxins, antimicrobic serum by immunising with micro-organisms. In some diseases both kinds of serum could be employed. 1. Diseases treated by antitoxic sera were diphtheria, tetanus, snake-bite, hay fever, dysentery, plague, typhoid fever, and tuberculosis. 2. Diseases treated by antimicrobic sera were streptococcal and staphylococcal infection, plague, typhoid fever, dysentery, pneumonia, anthrax, tuberculosis, Malta fever, and relapsing fever. 3. Diseases treated by sera of uncertain nature were small-pox, pertussis, yellow fever, syphilis, general paralysis of the insane, epilepsy, and cancer. Many of these so far had yielded no certain results and workers publishing uncertain and immature results deserved severe censure. The results of the antisera introduced by Maragliano and Marmorek for tuberculosis were unsatisfactory. A serum had been prepared which protected animals against pneumonia, but this was not as yet efficacious as a curative agent for man. Sclavo of Sienna had had fair results with anthrax. The antitoxin treatment of diphtheria had been eminently successful. It was introduced in 1894 and elaborate reports had been drawn up by the medical superintendents of the fever hospitals dealing with 10,700 cases of diphtheria, 5000 of which had been treated with antitoxin. Dr. Goodall quoted figures showing the rapid decline of the case-mortality from 22·8 in 1895 to 11 in 1902 as the percentage of cases treated with antitoxin rose from 61·8 in 1895 to 87·9 in 1902. The recovery-rate after tracheotomy had more than doubled since the introduction of antitoxin; the records of the Asylums Board showed that during the years 1889 to 1894 [illegible] cent. recovered after tracheotomy and [illegible] inclusive 62·9 per cent. recovered. [illegible] paralysis had increased since the introduction of antitoxin. Severe cases, or cases seen late in the course of the disease, which without antitoxin must have had a fatal termination were enabled with antitoxin to survive. Dr. F. J. Woollacott had given details in the Asylums Board reports for 1898 and in THE LANCET in 1899.[1] The result of the treatment of tetanus by antitoxin was not so striking as was that of the treatment of diphtheria; but this could not be expected when it was remembered that the treatment was not in most cases administered until spasms had set in, and spasms in tetanus corresponded in point of time to paralysis in diphtheria—i.e., they were due to the remote effects of the toxin. The experimental basis of treatment of snake-bites was sound maize. Injected subcutaneously into a susceptible person the toxin produced local and general symptoms of hay fever. Horses were inoculated with the toxin and their serum contained an antitoxin which promised to act remedially when applied as a remedy for hay fever. The serum of Yersin, of Lustig, and of others had not been very successful with plague and the Indian Plague Commission had not reported favourably upon it. In dysentery the results of serum treatment were not so far very promising. It was difficult to form a correct conclusion as to the result of the serum treatment in typhoid fever because the mortality of that disease varied greatly within limited periods of time and in statistics the age of the patients, an important factor in comparing mortality rates, was frequently omitted. The Chantemesse serum treatment was employed in 186 cases in a Parisian hospital from April 1st, 1901, to Dec. 1st, 1902, with a mortality of 3·7 per cent. During the same period in other hospitals in Paris 1478 cases treated with ordinary methods had a mortality of 19·3 per cent. Dr. Goodall believed that most obstetricians would endorse the conclusion of the committee of the American Gynæcological Society that they could find no proof that antistreptococcic serum would improve the results in the treatment of streptococcic puerperal infection. There were different strains of streptococci and a polyvalent serum had been produced the organi ictic uses of The passive immunity conferred by antisera seldom lasted longer than a few weeks. Dr. Goodall then discussed the question of standardisation, the factor on which correct dosage so greatly depended. Ehrlich's "unit" had been accepted as the standard for diphtheria in most countries; in France Roux's standard was still employed. The dose of diphtheria antitoxin was measured by "units", the doses of tetanus and snake bite antitoxic sera were measured in terms of so many cubic centimetres. The standardisation of the antimicrobic sera was in a chaotic state. Dr. Goodall's experience with diphtheria had led him to conclude that it was unnecessary to give more than 16 000 units of antitoxin within 24 hours of the commencement of treatment and in proof of this conclusion he submitted a table of 475 classified cases of diphtheria. There was no doubt that the earlier the case was treated the more favourable was the prognosis. From 2000 to 15 000 units were given within 24 hours of the commencement of treatment, either in one dose or in two or three at intervals of a few hours; the age of the patient should not be taken into consideration. Dr. Goodall then discussed the dosage in tetanus, snake poison, plague, typhoid fever, streptococcic infection, and hay fever. The usual *method of administering these sera was by subcutaneous* injection and this Dr. Goodall thought would continue to be the method most in vogue. Reference was made to the eruptions sometimes following hypodermic injections, sometimes immediately, sometimes after an interval of several days. He was not aware that there were any contra-indications to the administration of antitoxin. In conclusion it would be noticed, he said, that the most striking success, clinical as well as experimental, had been reached in the toxæmic diseases rather than in the infections.

---

[1] THE LANCET, August 26th, 1899, p. 561.

Professor S. H. C. MARTIN (London) referred to two experiments with snake venom made by Professor T. R. Fraser: (*a*) toxin and antitoxin were mixed in a glass and injected into an animal and it was determined how much antitoxin was required to neutralise the toxin; (*b*) toxin was injected into one flank of an animal, antitoxin into the other, and it was found that much more antitoxin was required to neutralise the toxin than in (*a*); and (*c*) a third experiment of his own in which he injected toxin subcutaneously and antitoxin into a vein and found that only the same amount of antitoxin was required to neutralise the toxin as in (*a*). The practical conclusion to draw from the last experiment was that antitoxin should be injected intravenously, not subcutaneously, when a patient had urgent symptoms.

Dr. F. FOORD CAIGER (London) emphasised with statistics the necessity of early treatment of diphtheria by antitoxin. Post-scarlatinal diphtheria had practically disappeared since the introduction and use of antitoxin. Polyvalent sera were required for the treatment of severe throat and glandular complications of diphtheria. He had tried injections of diphtheria antitoxin combined with antistreptococcic *serum in such cases with poor results.* He referred to the rashes consequent on the administration of antitoxin; these were sometimes accompanied by muscular pain, pyrexia, and arthritis, and it was noticeable that such severe serum reactions appeared *only after* an incubation period of about nine days. Local trouble at the site of inoculation of antitoxin was of considerable severity in some adults but children rarely suffered at all. Owing to these after effects he advised early administration of antitoxin, even on suspicion, to young children, but recommended waiting in the case of adults and older children. The dose should be regulated according to the severity of the case; the age and size of the patient were unimportant. Intra*venous injection of antitoxin should be employed in cases* with urgent symptoms.

Dr. W. BULLOCH (London) said that the serum treatment of disease was practicable and a comparatively simple matter in the case of toxæmic diseases, such as diphtheria and tetanus, where only the toxins entered the blood and all that was required was an antitoxin to neutralise the toxin. The case was entirely different and infinitely more complex when the germs themselves entered the blood (as in streptococcal infection, tubercle, typhoid fever, and most microbic diseases) and something was required which would dissolve the bacteria—a bacteriolytic serum. In such conditions Ehrlich had shown that intermediary factors were required, the *immune body and the complement.* The immune body was obtained from the serum of the animal and had to combine with the complement manufactured by the cells of man. This process was very complex, as anti-immune bodies might be injected into man at the same time and it was impossible to say beforehand whether in giving such serum as a remedy one was not actually lessening the patient's power of resistance and aggravating his disease. Antimicrobic sera, he concluded, should not be employed; at present the only hopeful outlook for such diseases lay in treatment by "vaccines."

Dr. GOODALL replied.

SURGERY

FRIDAY, JULY 29TH

Professor J. DEAVER (Philadelphia) read a paper on

Hepatic Drainage.

At the present time the opin certain phenomena produced biliary tract certain inflammatory changes, in every instance *for the formation* of gall stones. Multiple pregnancies, indiscretions in diet, sedentary habits, a dependent fundus and torpidity of the bile secretion might predispose to, or favour, disease of the gall bladder wall, but had no influence whatever in the formation of the calculi. The liver, the gall bladder, and the ducts became infected by the ascent of bacteria from the duodenum by way of the common duct or by an infection of the liver from the blood in the portal vein. Experimental investigations, post-mortem proofs, and clinical *experience were teaching* that the ascending infection, heretofore believed to be the nearly sole source, could not be responsible for many infections of the bile tract. Quoting from Adami they might assume (1) "that the colon bacilli in small numbers are in the healthy individual constantly finding their way into the finer branches of the portal circulation; and (2) that one of the functions of the liver is to arrest the further passage of these bacilli into the general circulation and to destroy them *through the agency* of the specific cells of the organ. Then if the action of the liver cells has been disabled by the toxic products of the bacteria these may reach the bile and spread through the gall bladder and ducts." Cirrhosis of the liver might be the direct result of infection ascending the common duct from the duodenum or through the portal circulation from the intestine. Literature contained many references to instances of this type of cirrhosis. Several observers had shown that when infected bile was obstructed by ligature the number of bacilli behind the point of obstruction became enormously increased. Many writers believed that the retained bile *per se* did not occasion biliary cirrhosis but that there must also occur inflammation of the bile ducts, cholangitis. In urging the possibility of

[illegible] too early removal of the rubber tube. Adhesions
[illegible] operation might inhibit the movements of the
[illegible]ing viscera and give rise to annoying disturbance of
[illegible]stro-intestinal tract, particularly of the stomach and
[illegible]num. The use of gauze for drainage should be limited
[illegible] as was compatible with safety and the gauze should
[illegible] guarded on the intestinal side with rubber tissue. By
these means the adhesions resulting were thin and filmy.

Professor RODMAN (Philadelphia) read a paper on

Carcinoma of the Mammary Gland; Early Diagnosis and Radical Operation necessary for its Cure.

He dwelt mainly on the numerous lymphatic connexions of the breast and pointed out that immunity from recurrence depended chiefly on a thorough removal of all the lymph nodes liable to be infected.

Mr. W. SAMPSON HANDLEY (London) read a paper on

Certain Defects in the Present Operation for Mammary Cancer,

based on investigations carried out in the Middlesex Hospital Cancer Research Laboratories. He pointed out that the invasion of the lymphatic plexus of the deep fascia by breast cancer was not an embolic process but that the cancer actually grew along the deep fascial plexus like a water weed along a network of irrigation channels, filling
[illegible] up. This process, to which subcutaneous and osseous
[illegible]ses were, in his opinion, secondary, might ultimately
[illegible] a centrifugal manner to the greater part of the
[illegible] the body, sparing only the distal portions of the

[illegible] Cases of Removal of Prostates.

[illegible] since the previous meeting of the
[illegible] and the prostates removed were
[illegible] ranged from 53 to 84 years and
[illegible] three-quarters of an ounce to 14[illegible]

[illegible] July 23rd, p. 197.

ounces with an average of three and a quarter ounces 13 of the cases were operated on in hospital and 44 in private practice One patient, aged 84 years, was an officer in the army, the prostatic symptoms had lasted for eight years and for five years he had been wholly dependent on the catheter The urine was fœtid and the patient was emaciated All the symptoms were completely relieved by the operation and the patient was now in excellent health. Another patient, aged 73 years, had had prostatic symptoms for 15 years and had been entirely dependent on the catheter for ten years and vesical calculi had been removed on two occasions. The prostate was removed entire in its capsule and it weighed 14¼ ounces The patient was now in good health and could micturate naturally. In another case retention of urine was not complete, although the prostate weighed 10½ ounces This was probably due to the fact that the prostate was greatly displaced from its normal position towards the bladder, so that there was not much lateral pressure on the urethra In contrast to this case several prostates were shown weighing from three quarters of an ounce to one and a half ounces in which there was complete dependence on the catheter Up to the present Mr Freyer had performed 110 operations of complete enucleation of the prostate It was found that in three of these the disease was carcinomatous Among the remaining 107 operations, there were ten deaths, five of which were from disease incident to old age and apart from the operation, but accepting these deaths as occurring in connexion with the operation they had a mortality of only 9 per cent, in comparison with a death-rate of 12½ from lithotomy in all ages, including children and of 34½ per cent from lithotomy between the ages of 55 and 80 years

In the discussion which followed Mr JORDAN LLOYD (Birmingham) showed a series of sections of prostates by which he maintained that it was proved that enlargement of the prostate was always due to the presence of adenomata

Dr H T HERRING (London) read a paper on the Cause and Effect of Enlarged Prostate, and Mr DANIELL (London) maintained that all cases of so called adenoma of the prostate were produced by overgrowth of the walls of the prostatic ducts and his paper was illustrated by a large number of micro photographs

STATE MEDICINE.

FRIDAY, JULY 29TH.

Mrs HELEN BOSANQUET who opened the discussion on

Poverty and Public Health,

said there was one section of the public which was below the standard of the better informed and it was this class that it became their duty to try to raise to a higher ideal Much of the sympathetic interest taken in the poor had from its injudicious methods done more harm than good but credit must be given to the workers for their good intentions The poor did not seem to realise how much those working among them cared for them, they had no desire to better themselves and it thus became a duty to try to arouse them to a higher standard of thought as regards dirt, overcrowding, foul air, and insufficient clothing A dirty home was, however, no claim for charity What was wanted was the improvement of general methods, not of details which would follow of their own accord A definite policy of reform was required among the many workers She did not believe that the state of their homes and absence of all hygiene were due to poverty in most cases but rather to the want of character and the remedy for this was education As regarded overcrowding and insanitation if the houses were improved and made wholesome the inhabitants in a short time made them foul and overcrowded them, while in new buildings, as a rule, only the better class of working people were admitted, the lower stratum going elsewhere and merely distributing the overcrowding The results had been failure An attempt had been made recently to supplement the children's food by meals at school but this only resulted in the mothers not giving them meals at home, while supplying them with sterilised or prepared milk was taken to mean that the mothers need not nurse their babies. In fact, milk was looked on as a medicine, not as a food The methods were not wrong but the application of them was, if the people could be made to take an intelligent interest in their homes and families all difficulties would disappear Mr. Rowntree had shown that the great majority could have healthy homes if they knew how to conduct them As a matter of fact, the very poor often did more than those better off Education was, in Mrs Bosanquet's opinion, the only remedy. Workers in all classes worked from their sense of responsibility, the natural state of man being slackness, hence every effort should be made to make the poor feel their responsibility The men must be made to take an interest in their families, for, as a rule, they knew little of them and only looked on them as a nuisance The intelligent feeding of children must be taught, especially those under school age All women and girls should be taught the care of children and this might be done by district visitors or at mothers' meetings. Some persons were so degraded that nothing would do any good to them and their children should be sent to day industrial schools

In the absence of Mr T P WHITTAKER, M P., his paper was read for him and he traced all the evils of the poor to abuse of alcohol and the waste of money on unnecessary things The majority of workers had plenty of money to live decently if they could only be persuaded to Drink in his opinion caused poverty Poverty did not lead people to drink The drunkenness of the father led to lowered vitality of the family The livers in the slums were there because they drink and they would not live in model dwellings because they might not overcrowd. The houses were what the inmates made them

Alderman HUGH HALL (Oxford) said that the housing question was a most unsatisfactory one and was not yet solved Town life was a permanent fact for many and was largely increasing In small towns there was some congestion but not nearly as much as in the big ones The urgent need of improvement was recognised but very little was being done In Oxford the chief trouble was bad houses there being very little overcrowding The mistake was to destroy houses and not to build new ones In fact, the bicycle was a better friend to the working man than the municipality, for it allowed him to live at a distance from his work in a decent home, while the municipality only turned him out if the area was overcrowded In his opinion the remedy for the evils was the rating of vacant sites, cheaper dwellings built on money borrowed at a low rate of interest, allowing a long time for repayment, and easier building laws Municipalities were not progressive or in favour of new methods The central authority—the Local Government Board—to which the medical officers of health should report on the deficiencies of the towns, should insist on the corporations putting their towns in order But he believed this would be better done by a new department In addition public feeling must be aroused

Dr G A HERON (London) believed that the education of public opinion was the remedy, but it was important to educate the parents, more particularly the mothers, in the care of their children Medical men were the best qualified to do this, though Lord Londonderry had said there were no teachers available and there would be none till 1906

Mr J STEWART (Clifton) thought that it would be best to educate the teachers to teach the children personal and domestic hygiene He believed drink was an important factor in the production of poverty Patient hard work on the question was required and in time a good result would follow

Miss T. JOHNSTONE believed many women could be found as willing workers and narrated her experience among the factory hands of Bristol

Dr J T WILSON (Lanark) referred to the difficulties in the way of obtaining sanitary reforms

Dr G F MCCLEARY (London) did not believe mothers neglected to give their children food because it was supplied at school The high price of milk was against its wide use, for the poor could not afford it He did not think everything could be done by education, as some speakers seemed to think, and he did not agree with Mr Whittaker that drink caused poverty

Mr W. MCADAM ECCLES (London) believed that poverty was due to indifference Education was the remedy to make men respect themselves more and stimulus after. He thought that water should be supplied free

Dr GROVES warned those who advocated education not to worry the Education Board It was anxious to do its best but did not like every one worrying it with his views.

Dr. ALICE DRYSDALE believed that as long as poverty was prevalent it was difficult to raise the standard of public health

Mrs. BOSANQUET, in reply, said that the taste for alcohol was an acquired one and she believed men drank from sheer vacuity of mind. In her opinion much harm was done in talking about the inherited tendency to drink. She believed it was best to drive the poor out of the towns; suitable dwellings should be erected in the outskirts. She was a strong believer in educating the people to the sense of their *degradation.*

Dr. A. E. BOYCOTT (London) read a paper on

Ankylostomiasis.

His observations were made among the Cornish miners, in whom examination was very difficult owing to the fact that they were not hospital patients. Anæmia was not a symptom to be relied on, as many suffered from the disease and did not show any anæmia. Examination of the fæces was impossible. In his search for a trustworthy means of discovering whether or not a man suffered from the disease he found that a blood examination was the best method, as there was a large increase in the eosinophile bodies. The method was not absolute but a good working one. (Several lantern slides were shown.)

Dr. KENNETH W. GOADBY (London) read a paper entitled

"*A Plea for Oral Hygiene, with a Suggestion.*"

Oral sepsis had recently been shown to be associated with many important diseased conditions and to be the portal of infection in some grave disorders. Dental caries was also important in the production of malnutrition, particularly in children, and might also be the origin of various sorts of stomatitis. In a certain number of well-authenticated cases death might supervene as a result of oral infection, while a considerable number of pathogenic organisms were known to inhabit the mouth from time to time. The pathology of dental caries and with it affections of the soft tissues of the mouth was found to be associated in a great measure with the alteration that had occurred during recent decades in the composition, both chemical and physical, of the national food-stuffs. There was apparently no definite change in the quantity of lime salt present in individual teeth. Children particularly gave evidence of affections of the nose and throat, associated with carious teeth and oral sepsis, whilst the number of children suffering from these two conditions was at least 80 per cent. With such a large number of the rising generation suffering from dental caries and oral sepsis, with their well-recognised effects upon physical development, the matter became one of national importance and required considering from the point of view of State medicine. The present methods of dealing with oral disease only touched the fringe of what was required to be done; although much was being done by the appointment of dental surgeons to schools, yet the number of dental surgeons in proportion to the number of children to be treated was hopelessly inadequate. The same facts held good for the treatment of cases in dental hospitals. The individuals who required treatment were divisible into three classes: (1) children in schools; (2) young adults, such as domestic servants and the like; and (3) the general mass of the working-class population. Amongst children those of from one year to five years of age were the ones who required special treatment, particularly prophylaxis. The other two classes required more particularly ordinary dental attention and instruction in hygiene. The following scheme was suggested with a view to dealing with this very difficult question: the appointment of a dental surgeon by groups of schools of two or more, together with the local sanitary authority, his work to consist of periodical inspection of the whole of the children once in three months or oftener; the treatment of dental caries and oral disease at some central place, to which the children could conveniently be sent; and the superintendence of the periodical cleansing of the mouths of all young children, which might be performed by an intelligent assistant under the supervision of the dental surgeon. It was also suggested that the medical officer of health for the district should be empowered to send to the dental surgeon for treatment cases of chronic stomatitis and like conditions, especially during epidemics of diphtheria. The local sanitary authority might provide the room and material necessary. For the treatment of the other two classes it was suggested that the existing machinery in the shape of dental hospitals should be enlarged in its scope of operation in the following manner: by the appointment of clinical assistants, qualified men, at a salary, including board, as paid to house surgeons of various hospitals; by a nominal payment being made by patients sufficient to cover working expenses; by the work undertaken being the treatment of dental caries and oral sepsis and not artificial teeth; by the clinical assistants being under the jurisdiction of the hospital staff; and by the existing arrangements of the various hospitals in determining the propriety of treating any doubtful case. The scheme would not be in opposition to the practice of the qualified man and it aimed at treating that class of the population which was largely attended to by unskilled and unqualified persons, with an increase rather than a decrease of oral sepsis.

Mr. C. W. J. BRASHER (Bristol) read a paper on

The Segregation of Tuberculous Patients among Factory Workers

and described the methods employed at the factories of Messrs. J. S. Fry and Sons in Bristol. Here there were 2000 girls and women under 54 superintendents all carefully selected from the numerous applicants. All tuberculous patients were suspended from work, put on the sick fund, and sent to a sanatorium as soon as possible. None of them were allowed to return but were assisted to find work elsewhere or were pensioned. A brief table was given which showed very satisfactory results.

During the meeting the following motion was carried:—

It is highly satisfactory to the State Medicine Section to learn that the council of the British Medical Association have exerted themselves to secure the education of public elementary school teachers in personal (including oral hygiene) and domestic hygiene in order that every child in public elementary and secondary schools may be instructed in these subjects; and they beg to request the council to continue their efforts in this direction.

PATHOLOGY.

THURSDAY, JULY 28TH.

A discussion on the

Rôle of the Lymphocyte

was opened by Dr. G. LOVELL GULLAND (Edinburgh) by a paper entitled "The Lymphocyte; its Nature, Origin, and Development." In entering a plea for unanimity of nomenclature Dr. Gulland referred to the four varieties of non-granular cells—viz., the large and small lymphocytes, large mononuclear, and transitional. Of these the first two are agreed to be identical, but difference of opinion exists with regard to the two latter. The large mononuclears, according to Ehrlich, were distinct from the lymphocytes and became converted in the blood into transitionals, which latter formed the connecting link between the mononuclears and the polymorphonuclear neutrophiles. Dr. Gulland, on the contrary, regarded the leucocytes, mononuclears, and transitionals as merely stages in the development of one type and in no way related to the polymorphonuclears, and he based his contention on the observed facts that in all these cells the cytoplasm was faintly basophile, gradations in depth of colour depending on the thickness and arrangement of the strands and nodes of the cytoplasmic reticulum; granules, he said, existed as nodal points of the cytoplasmic reticulum, though often obscured by the thick strands; differences in the shape and position of the nucleus depended, according to the researches of Heidenhain, on the pull exerted by radii which were embedded in the cytoplasm and which diverged from the centrosome, astrosphere, or attraction sphere, in their endeavour to bring the astrosphere to the centre of the cell whilst the cell was at rest. The nucleus—the chief obstacle—was first pushed to one side, then deformed, becoming first kidney-shaped and afterwards horseshoe-shaped. The greater size of mononuclears and transitionals was explained as being due to absorption of fluid. Finally, the cells were classed into lymphocytes on the one hand, and neutrophiles, eosinophiles, and basophiles or mast-cells on the other. In adult life these two groups of cells were distinct and reacted differently to stimuli; the first were found normally in the blood, the second in the marrow. The point of origin of the lymphocyte was stated as the lymph glands and the lymphatic tissue of the tonsils, intestine, spleen, &c., although numerous lymphocytes could be demonstrated in the healthy marrow; indeed, in the marrow of young animals the lymphocytes still often outnumbered the rest of the cells. The view still held by some that lymphocytes could be derived from endothelial cells was adversely commented upon. In conclusion, Dr. Gulland held that the function of the lymphocyte was no doubt largely protective, especially when present in lymph glands and in this connexion an interesting point was raised in that the chief habitat of lymphocytes apart from lymph glands and marrow was the lymphatic tissue around the hollow tubes of the body—alimentary and respiratory tracts—spots occupied by saprophytic, non-virulent, or attenuated organisms.

Professor ROBERT MUIR (Glasgow) then read a paper entitled

Some General Considerations regarding the Relations of the Lymphocytes, as indicated by Pathological Conditions,

pointing out how easy it was to make in all good faith a series of transition forms from the small lymphocytes to all the members of the leucocyte class and the fallacy of concluding that any one variety might be transformed into any other according to circumstances In his opinion the chief considerations in connexion with the subject were the phylogenetic and ontogenetic development of the different classes of leucocytes, the character of the cells undergoing active development, and their sites of multiplication and the general behaviour of the different varieties under pathological conditions He agreed with Dr Gulland that the hyaline wandering cell with oval nucleus might be taken as the primitive type; next to this he would place the coarsely granular eosinophile—a well developed and common type of cell even amongst the lower animals—which appeared in the mammalian embryo at an earlier date than the finely granular cell, while the cells with well-marked neutrophile granules did not appear until the fifth month. In the bone marrow non granular cells with basophile protoplasm accumulated first and afterwards acquired neutrophile granules Non-granular cells multiplied in the germ centres of lymphoid tissue and finely and coarsely granular cells in
eosinophiles multiplied in either
ls in large numbers were chiefly
chronic conditions, eosinophiles
were attracted by special chemotactic substances in relatively non-acute conditions, while the finely granular cells were chiefly concerned in acute bacterial infections. In inflammatory conditions non-granular cells acting as phagocytes were also derived from the larger lymphocytes of the blood and from certain cells, normally fixed or sessile, and it became impossible to assign the source of origin to any given example, though Professor Muir had studied their course of development in lymphatic glands Further, the opinion was expressed that there were homologous, fixed or clasping cells which in inflammatory conditions became spherical in form and acted as phagocytes by a process of reversion to a mor
converse did not hold good On
to a normal condition the large
in size and assume the appearances of the small inactive lymphocytes The suggestion was advanced that in the mixed celled leukæmias cells were present which represented the non granular precursors of myelocytes that were seen in embryonic life and the possibility was raised that in some cases of lymphatic leukæmia the large lymphocytes might have been derived from the clasping cells of connective tissue

Dr J. M BEATTIE (Edinburgh) was then called upon for his paper on

The Lymphocyte in Inflammatory Exudations,

in which he pointed out that much of the difficulty experienced in studying the mononuclear cells of inflammatory exudations was due to the use of stained preparations alone and might be avoided by observing the cell in its living condition on the warm stage and by the experimental study of its developmental history Another difficulty consisted in the accumulation of various kinds of cells at the site of irritation in the early stages of inflammatory processes, many of which had migrated from distant parts, others being produced locally by proliferation of endothelial cells and fixed connective tissue cells Dr. Beattie had confined his work chiefly to the investigation of the peritoneal fluid and omentum in acute peritonitis following experimental injections of bacilli coli and the more chronic conditions produced by bacilli tuberculosis Referring to the lymphoid cells, he stated that these were present in the form of a sheath surrounding the vessels and were also collected in masses or nodules of varying size In early stages of the inflammatory process the differentiation between lymphoid and endothelial cells was well marked The *source of these masses of lymphoid cells was still in* dispute, but Dr Beattie's experiments supported the views of Ribbert, who contended that they were produced locally from pre existing lymphatic tissue, normally present though but little developed The importance of the cytology of serous effusions to the clinician was remarked, although Dr Beattie considered cerebro spinal fluid or pleural fluid rich in lymphoid cells did not necessarily indicate tuberculosis but merely a condition of chronicity In acute inflammatory exudations transition stages between the lymphocyte and large mononuclears were numerous, and he was distinctly of opinion that lymphoid cells did increase in size and the fact that so few transitional cells were present in the blood was explained by the assumption that they were formed in pre existing lymphoid tissue outside the vessel and only a few were washed in by the overflow from lymphatic channels or possibly by migration As to the function of these lymphoid cells, Dr Beattie had never observed phagocytosis by the smaller forms, but the larger forms were undoubtedly phagocytic, and he explained the difference by assuming the smaller forms to be younger and less functionally active Speaking of the clasmatocytes described by Ranvier he regarded them as derived from large mononuclear cells in a condition of active amœboid movement or from endothelial cells Mononucleated phagocytes played an important part in the early stages of infection and in the later stages were almost the only cells present With regard to the question of the formation of fibrous tissue by lymphocytes his observations were not sufficiently advanced to permit him to put forward definite opinions

Dr J H DRYSDALE (London) then read a paper on

The Clinical Significance of Lymphocytosis,

in which he confessed that he had under-estimated the difficulties of forming a just opinion of the clinical significance to be attached to the presence of a lymphocytosis Defining lymphocytosis as an increase beyond the limits observed in health of the absolute number *of lymphocytes in the circulating peripheral blood*, he pointed out the advantage of eliminating by this definition all conditions in which there was merely decrease in the number of polymorphonuclear leucocytes, the lymphocytes remaining constant, and advocated returning all differential counts in absolute numbers per cubic millimetre As a rough standard he counted 7500 leucocytes per cubic millimetre, made up of 5000 polymorphonuclears, 2000 lymphocytes, 350 large mononuclears, and 150 eosinophiles Briefly discussing what may be termed the physiological lymphocytosis of early and of adult life he passed on to lymphocytosis associated with pathological conditions, confining his remarks chiefly to those conditions in which the lymphoid tissue was affected and in which the number of lymphocytes in the circulating blood was increased Speaking of Hodgkin's disease which was variously regarded as the leukæmic stage of lymphatic leukæmia, lympho sarcoma, and tuberculosis, Dr Drysdale gave the result of his observation on 14 cases occurring in St Bartholomew's Hospital—cases in which he had examined the lymphatic glands during life or had made a post mortem examination The degree of blood change was usually moderate in all Six cases gave a total count of 6000 leucocytes or under while six other cases gave 10,000 or over Seven cases gave less than 5000 polymorphonuclears and seven cases gave over that number, seven cases gave under 2000 lymphocytes and in seven there were 2000 and over When the numbers obtained were over the normal there was an absolute increase of polymorphonuclears and lymphocytes without alteration of the respective ratios, consequently he could not regard the blood changes as symptomatic. So also in lympho sarcoma the lymphocytes might be greatly increased but usually the blood changes were trifling and negative Lymphocytosis, when it did occur, afforded no conclusive information and in the majority of cases it was at present impossible to explain even tentatively an increased number of lymphocytes in the circulation

Dr W. G MACCALLUM (Baltimore) then read a paper entitled

The Relation of the Lymphocyte to the Lesions of Typhoid Fever

Referring first to the presence in typhoid fever of very large cells in the lymphoid structures of the intestine and mesentery to which the name "typhuszellen" had been applied, he pointed out that these had been described by some workers as swollen lymphoid cells become motile and phagocytic, and by others as proliferated and desquamated endothelial cells derived from the fixed cells lining the reticulum of lymph glands, &c, or even of the venous channels—a proliferation due, according to Mallory, to the action of diffusible toxin. Examination of the blood during the height of the disease showed that there was undoubtedly a definite leukopenia due to a decrease in the polymorphonuclear leucocytes, whilst after an initial fall the relative and absolute numbers of lymphocytes were greatly increased. Dr. MacCallum's observations on the condition of the blood-forming organs in typhoid fever were chiefly based on the study of a fatal case of meningitis occurring during a typical attack of typhoid fever (from which a pure culture of the bacillus typhosus was obtained from the cerebro-spinal fluid drawn off during life by means of lumbar puncture), in the course of which it was found that in a simple tissue such as the pia, possessing normally but very little lymphoid tissue, infection with the typhoid bacillus would produce abundant appearance of lymphoid and allied cells in addition to other changes. Noting the uniform appearance and small size of the lymphoid cells in Peyer's patches he contrasted these with the large cells possessing similar nuclei found in considerable numbers in the lymphoid tissue of the intestine and incidentally mentioned that he had traced their development into very large cells indeed. In typhoid fever there was a distinct chemiotactic influence over the lymphocytes which responded by wandering out of the vessels and into the tissues which were exposed to the action of the toxin, and the increased demand was met by the increase and new formation of lymphoid cells in the bone marrow.

Dr. A. R. FERGUSON (Glasgow) read a paper on

The Relation of Lymphocytosis to Small-pox,

in which he showed that as a result of his study of the leucocytic changes occurring in the blood, and therefore reflected in varying degree by the different body tissues, there was (in variola) an excessive production of cells of the lymphocyte and smaller hyaline classes. These were found in very high proportions in the blood and in the skin; in fact, in the skin they formed a notable constituent of the exudation in the earlier stages of the eruption. In the blood, however, they reached their highest proportions, after the virus had presumably left the blood to enter the skin. These changes were accompanied by considerable activity of the lymphocyte-producing tissues throughout the body. According to Dr. Ferguson the subcortical lymphoid follicles of the lymphatic glands were chiefly concerned in the process, although the Malpighian bodies of the spleen also played a contributory part in producing the lymphocythæmia. Cells of the neutrophile class, on the contrary, underwent a progressive diminution relatively, any initial activity on the part of the bone marrow being soon replaced by a passive condition or even in severe cases by one in which all the leucoblastic elements were destroyed.

Dr. T. HOUSTON (Belfast) read a paper on

Lymphocytosis, with Special Reference to the Rôle of the Lymphocyte in Leukæmia,

in which support for the contention that all the cells of the lymphocyte groups, both typical lymphocytes and large mononuclear cells, had their origin in the lymphatic tissues generally was found in the fact that different types of lymphocytes were represented in some cases of lymphatic leukæmia, for the essential morbid change in this disease was excessive lymphatic proliferation. The large mononuclear cells so often represented in large numbers in cases of lymphatic leukæmia were regarded as undoubtedly amœboid and phagocytic and evidence was adduced that even lymphocytes proper possessed some degree of motility. Commenting on the clinical resemblance and similarity of the blood pictures of both spleno-medullary leukæmia and lymphatic leukæmia to septic processes Dr. Houston quoted first a case of acute sepsis and then a case of pneumonia in which the blood pictures closely simulated spleno-medullary leukæmia and lymphatic leukæmia respectively. It was also pointed out that sepsis might produce a leucocytosis which in the child was mainly a lymphocytosis and in the adult mainly a polymorphonuclear leucocytosis, and contrasted with the leukæmias which in early life were mainly of the lymphatic type, while those of the adult were characterised by an increase of the granular cells—myelocytes and polymorphonuclears. Referring to the cases of "mixed-celled" leukæmia which had been described by Wolff the comparatively common occurrence of mixed-celled leucocytosis in children was mentioned, Dr. Houston's observations confirming those of Wolff and others.

Dr. C. H. MELLAND (Manchester) read a paper on

The Lymphocyte in Leucocythæmia,

which was illustrated by an excellent series of coloured lantern slides. He pointed out that in the chronic lymphatic form of leucocythæmia the majority of the lymphocytes had the same character as normal small lymphocytes and doubtless originated in the lymphatic glands, in which there was evidence of increased proliferation; and also in the bone marrow, where the granular cells were replaced by lymphocytes. In acute leucocythæmia, on the other hand, the lymphocytes met with in the blood had very different characters, the cells were very much larger, the nuclei were round or oval, and the narrow zone of cytoplasm stained more or less deeply basophile. In spleno-medullary leucocythæmia large lymphocytes were present in considerably increased numbers in addition to the myelocytes with neutrophile granules. In Dr. Melland's opinion, there was a degradation in the character of the cells in the blood; the myelocyte was a less highly differentiated cell than the polynuclear neutrophile, and these large lymphocytes represented a further retrograde step. That this degradation might be progressive was evidenced by the fact that the blood picture of spleno-medullary leucocythæmia might be replaced by that of lymphatic leucocythæmia in the course of the disease, though the reverse condition had never been recorded.

Dr. T. GILLMAN MOORHEAD (Dublin) then communicated a

Preliminary Report on some Investigations into the Etiology of Leukæmia.

After briefly reviewing the parasitic theory of Löwitt and mentioning the hæmamœba leukæmiæ magna of that author, he referred to the inconstant occurrence of streptococci in the blood of leukæmia patients and then passed on to a discussion of the toxic theory which, however, was not necessarily antagonistic to the parasitic theory. The points in favour of the view that a toxin stood in etiological relationship to the disease were summed up: (1) many cases were preceded by some other disease which had lowered the general resistance of the organism; (2) inflammatory conditions of the mouth, stomach, and intestines frequently preceded or accompanied the disease; (3) peptones and uric acid could be found in the blood of leukæmia patients and said to be accompanied by excess of peptones in the spleen; (4) repeated injections of peptones caused continued leucocytosis in animals; (5) there was lowered coagulability of the blood; (6) evidence in the urine of increased breaking down of tissue, together with deficiency of metabolism; (7) the occurrence of capillary hæmorrhages; and (8) the occurrence of areas of necrosis in various tissues. As the result of the examination of 135 grammes weight of lymph glands obtained from a patient suffering from the lymphatic form of leukæmia, Dr. Moorhead after precipitation with alcohol was able to extract a substance with saline solution, a substance which produced a marked fall of blood pressure in rabbits. This depressor substance, as shown by control extracts from normal glands, was not a normal constituent of ordinary lymphoid tissue. The depressor substance was possibly a specific toxin because continuous injection of the extract containing it produced marked changes in the hæmopoietic tissues in rabbits—changes not confined to any one of those tissues but involving them all, and the rapid development of the changes was ascribed to the large quantities of toxin injected on each occasion.

One of the secretaries of the section then read a paper by Dr. F. G. BUSHNELL (Brighton) on

The Rôle of the Lymphocyte,

in which the belief was expressed that the large lymphocyte was younger than the small, that the granular myelocyte or marrow cell formed granular cells mainly, the lymphoid cell of adenoid tissue producing non-granular cells. Lymphocytosis was stated to be physiological in infants and young children, in pregnancy, lactation, and following digestion; it accompanied pathological conditions such as anæmia, leukæmia, sarcomatous growths, bacillary diseases, syphilis, &c.—in fact, it always occurred in conditions in which nutrition and metabolism were at an unusual balance, and in general terms lymphocytosis might be interpreted as indicating response to disturbances of lymphoid tissues by physiological or by toxic agencies. The paper then discussed the relationship of lymphocytosis to various pathological conditions, such as granulation tissue formation and small round celled sarcomata, the anæmias and leukæmias, the points being illustrated by a selected series of blood counts from typical cases

On the conclusion of the day's sitting several highly interesting demonstrations were given The first, by Dr A E WRIGHT (London), consisted of a demonstration of the Preparation and Use of the Collecting and Measuring Pipettes (simple and "throttle") which he had introduced for blood estimations serum examination, routine bacteriological work, &c The second, by Dr R N SALAMAN (London), was a demonstration of the Reservoir Action of the Nutmeg Liver in Cardiac Disease, illustrated by diagrams and three colour process lantern slides, adducing reasons for regarding the liver as a safety valve for the right heart which by continued use lost its value and shortened very greatly the field of cardiac response —Dr I WALKER HALL (Manchester) then demonstrated the Methods of estimating Purin Bodies by Means of his Apparatus known as the Purinometer

---

LARYNGOLOGY AND OTOLOGY

WEDNESDAY, JULY 27TH

This section met under the presidency of Mr CHARTERS J SYMONDS (London) A discussion on

The Treatment of Non Suppurative Disease of the Middle Ear

was opened by Dr URBAN PRITCHARD (London) and Dr THOMAS BARR (Glasgow)

Dr PRITCHARD classified the conditions included under non suppurative disease of the middle ear for the purpose of [illegible] the following divisions [illegible] media, (2) early stages of [illegible], (3) advanced stages of the same, (4) middle ear adhesions the result of former acute inflammation, and (5) sclerosis resulting from disease of the bony capsules inclosing the internal ear and forming the inner wall of the tympanic cavity

1 *Treatment of acute otitis media* —In the earlier stages, he said, gentle, not forcible, politzerisation (not catheterisation) would often relieve the pain at once and tend to cut short the attack Counter irritation behind the ear was always most valuable and would often arrest the *otitis* and relieve the pain Instillations were occasionally advisable and when used should be strong anodyne solutions—for example, cocaine or morphine in an antiseptic medium, glycerine of carbolic acid had been strongly recommended, also adrenalin with cocaine Heat in the form of very hot fomentations or hot bran bags was very useful, leeches in front of, and below, the ear were valuable in very acute cases Incision of the membrane was called for when there was marked bulging, the meatus must be purified and afterwards dressed antiseptically to avoid suppuration Purgatives were nearly always necessary Pharyngeal treatment was usually required but nasal douches or irrigations must absolutely be avoided As regarded after treatment politzerisation should always be employed, it would restore the hearing and prevent adhesions If adenoids were present they should be removed

2 *Treatment of the early stages of chronic non suppurative catarrh*, in which there was exudation into the mucous membrane and from its surface with resulting stenosis of the Eustachian tube and more or less fluid in the tympanic cavity In this group of cases Dr Pritchard said that politzerisation was preferable to catheterisation, it should be repeated at intervals of one two, or three days according to the relief obtained, as ascertained by the amount of improvement in the hearing it should not be continued when *it increased the deafness Incision of the membrane* might [illegible] *and in the tympanic* cavity [illegible] condition Local medici[illegible] sterile alkaline nasal irrigation (e g, borax and sodium bicarbonate) was to be preferred to the nasal douche as the latter occasionally produced acute otitis, inhalations of pine oils eucalyptus oil, or, still better, of fumes of ammonium chloride were most valuable Climatic treatment was important, damp situations should be avoided and high, dry, and sunny positions should be selected, warm and well drained seaside resorts were good, whereas cold, damp seashores with a northern aspect must be avoided High sunny Alpine valleys were often very beneficial, but on rapidly descending from these Valsalva's inflation should be practised Early and continued *treatment of these stages of catarrh* was most important and would often prevent the advanced stages

3 *Treatment of advanced stages of middle ear catarrh* —This he considered was much less satisfactory on account of the adhesions causing retraction of the membrane and fixation of the membrane and ossicles Catheterisation was often preferable to politzerisation, but the value of courses of repeated inflations had been much over-rated, patients, he said, should be warned against the constant recourse to Valsalva's method of inflation, at the same time, cautiously employed, it was of value Gentle suction by means of Delstanche's masseur was occasionally of value but might easily be overdone The Eustachian bougie had been over valued, the objection to its use were firstly the risk of injury to the delicate ciliated mucous membrane, the narrow part of the tube being bony it could not be dilated except at the expense of this mucous membrane Secondly, in advanced cases the loss of hearing power was almost always due to changes in the tympanic cavity and not in the Eustachian tube Speaking of operations he said that all these up to the present had been futile in this particular group of cases As regarded local medicinal treatment, nasal irrigations of sterile alkaline and saline solutions were of much value Inhalations of the ammonium chloride fumes with cautious Valsalva's inflation to introduce them through the Eustachian tube formed a most valuable treatment, but long continued use with intervals of rest was necessary Injections through the Eustachian catheter were much employed by some surgeons and were occasionally of value, probably a sterile solution of sodium bicarbonate was the most efficacious Speaking of internal medicinal treatment, he said that occasionally when the mucous membrane was glazed and dry small doses of potassium iodide with ammonia—so as to produce slight symptoms of coryza—combined with some form of inflation would yield excellent results Turkish baths were of value in some of the less advanced cases

4 *The treatment of middle ear adhesions of old standing* —This he considered was most unsatisfactory, operative interference had up to the present signally failed though there might be a future for it In fact, at present these cases only made the surgeon regret that active treatment was not adopted directly after the acute inflammation which resulted in the adhesion

5 *Treatment of sclerosis* —This he said was still more hopeless and in a pure case no treatment was of any avail—mechanical medicinal operative, and climatic treatment were alike useless All that one could do was to use such treatment as would keep up the general health in the hope that thereby a tendency for the disease to become arrested would be established Aurists had yet to learn whether the high frequency electric treatment would yield any results In conclusion, Dr Pritchard said he knew of no condition in which treatment should be considered more judicially, avoiding hasty conclusions for or against any proposed treatment, and that they ought certainly not to judge harshly of over-enthusiastic *confrères* who might be unduly vaunting some new process having been carried away by a few apparent successes

Dr THOMAS BARR limited himself to the non exudative or dry forms of the disease whatever their origin might have been The problem to be dealt with, he said, was more difficult than in the exudative forms there were usually changes and products in the middle ear which might have originated long before sometimes during early childhood in acute inflammation in simple exudative catarrh, or, worst of all in gradual and scarcely perceptible changes of a dry nature from the beginning The scientific character of the treatment was faulty because of the deficiency of knowledge of the anatomical changes existing in *any given tympanum* and efforts of treatment were on that account bound to be often empirical and to some extent experimental The field of treatment was large but not proportionately fruitful It was manipulative, operative medicinal, hygienic and climatic Amidst the diversity of opinion regarding the value of the different methods inflation in some form or other, but especially in the form of politzerisation was probably practised by all otologists In view of the fact that it was rarely possible to determine the precise conditions of the intra tympanic structures in any given case one was not often justified in excluding the possibility of doing good until the test of treatment, especially the test of effective inflation had been applied Any increase in the deafness or in the intensity of the subjective sounds called for an immediate halt, whereas improvement, even although comparatively slight, would encourage the continuance of these efforts. Inflation should not be practised too frequently, seldom more so than every second or third day; too prolonged treatment was bad; after three or four weeks there should be a pause of one, two, or three months, and in some cases short courses of such treatment might be required at intervals during the whole course of a person's life. Patients or friends could usually, be taught to inflate efficiently, but then definite directions as to the frequency and duration of the treatment should be given with the warning that if any increase in the deafness or subjective sounds be observed the fact should be immediately reported. Valsalva's method of inflation, he considered, was rarely permissible because the patient was either unable to inflate his tympanum or did great mischief by unduly frequent repetition, so that it was not uncommon to find a patient repeating it before every interview, perhaps 20 or 30 times a day, and acquiring such dexterity that the act was scarcely perceived by the onlooker; the improvement in hearing in consequence became less and less, and shorter and shorter, with gradually increasing mischief to the function of the organ. Efforts to force vapours through the Eustachian tube into the tympanum were generally futile. Probably the best results were obtained by the sudden impact of air yielded by Politzer's method, and catheterisation was limited to the cases in which the introduction of solutions or vapours into the middle ear was indicated or where stricture existed in the Eustachian tube. Applications to the inside of the tube itself through the medium of the catheter were productive of good. Paroleine solutions of iodine, menthol, camphor, cocaine, and adrenalin might be introduced through the catheter with good effect by means of an atomiser in catarrhal swelling of the Eustachian tube. The treatment of organic stricture of the Eustachian tube was very unsatisfactory and an attempt to dilate forcibly such a stricture by means of some kind of bougie seldom led to a good result. In regard to the value of nasal treatment, he said that probably most otologists would approve of operating upon the naso-pharynx when post-nasal adenoids existed, without, however, expecting such brilliant results as in the case of the exudative catarrhs. There could be no doubt that nasal obstruction, especially when severe, tended to exercise an injurious influence upon the tympano-Eustachian apparatus. There was a good deal of agreement as to the propriety of operative or other treatment when there were hypertrophic changes in the nasal passages, but the existence of a small spur or knot on the septum, interfering very little or not at all with nasal breathing and producing no special tendency to catarrhal attack, should probably be ignored. There were cases in which intranasal operations had seemed to aggravate deafness, perhaps through nervous shock or from the entrance of blood into the Eustachian tube, while the nasal douche might in the absence of careful precautions be productive of much harm. The so-called pneumatic massage of the tympanum along with inflation was suitable; even in sclerosis it frequently allayed tinnitus. The use of friction with the aid of a stimulating ointment such as camphor, oil of peppermint, and vaseline, applied behind and below the ear in the form of a kind of massage, seemed often to be productive of good. Speaking of the value of operative treatment on the tympanic membrane and intra-tympanic structures, he said that with a narrow meatus many of such operations were well-nigh impossible, while in the absence of an exact knowledge of the pathological conditions in the tympanum the operator was in the position of one groping in the dark. An artificial perforation with a galvano-cautery might improve the hearing or relieve the tinnitus, if such an opening could be made permanent. In proceeding to the other and deeper operative measures there was a greater danger of injuring rather than of improving the hearing. Electrical treatment, he said, long in abeyance in aural therapeutics, had been again revived in the form of high-frequency currents. The results had been sufficiently encouraging to justify further trial, although no doubt the treatment was entirely empirical. Dr. Barr, in conclusion, offered suggestions for further investigation of the subject and considered that by a well-defined and pre-arranged plan of working it would be possible to determine the true value of individual methods of treatment.

In the general discussion which followed

Dr. ADOLPH BRONNER (Bradford) advocated constitutional as well as local treatment. He expressed himself opposed to the use of Politzer's bag on account of not being able to obtain by means of it uniformity of pressure. The practice of intrusting the use of the bag to patients he considered should be condemned. In the divergence of opinions as to nasal obstruction being a factor in the production of the varieties of deafness under discussion he thought there was room for charity and mutual concessions.

Dr. MARCEL NATIER (Paris) demonstrated a series of diagrams illustrating the treatment of deafness by means of tuning forks.

Dr. J. WALKER DOWNIE (Glasgow) recommended treatment of adhesions of ossicles by means of Valsalva's method as beneficial when gently applied; he also was in favour of a nebuliser in place of Politzer's bag. Speaking of the treatment by high-frequency currents, he said that out of a dozen cases which had been treated for him only one had improved after daily applications for 15 minutes extending over six months, a very serious tax upon the patient.

Mr. F. MARSH (Birmingham) advocated the removal of anything which interfered with free drainage and free airway. He recommended oily injections. His experience of high-frequency currents was unfavourable and he had seen more harm than good from Valsalva's method.

Dr. W. MILLIGAN (Manchester) considered that otology should be made a compulsory subject in medical education. He spoke of the value of physiological rest in middle-ear catarrh. Seaside air he considered injurious but high altitudes beneficial. In sclerosis he had found iodide of potassium of value. Patients he had observed under treatment with high-frequency currents had become rather worse than better.

Dr. L. H. PEGLER (London), speaking with reference to the exudative variety, expressed himself in favour of leaving the fluid in the tympanic cavity to be absorbed and of not doing a paracentesis. Regarding the diagnosis it was often uncertain, the patient's condition being a mixed one. Allowance had to be made for the neurasthenic element in the tuning-fork test.

Dr. R. H. SCANES SPICER (London) spoke with reference to nasal obstruction as a factor in the etiology.

Dr. H. SMURTHWAITE (Newcastle) said that his experience had been similar to that of the previous speaker in the frequency of nasal obstruction as a factor in the deafness.

Dr. E. B. WAGGETT (London) was in favour of educating any hearing power that might be left and laid stress on the importance of differentiating a sclerotic condition of the middle ear at the first visit of the patient.

Dr. C. E. SHAW (Belfast) emphasised the necessity of early treatment. The vibration treatment he regarded as altogether useless.

Mr. C. H. FAGGE (London) considered that more definite knowledge of the pathology of the subject was required. He was also opposed to patients being intrusted with Politzer's bag.

Mr. G. W. HILL (London) spoke favourably of Delstanche's masseur for relieving tinnitus and improving the hearing.

Mr. A. J. BRADY (Sydney, N.S.W.), speaking of the value of operative measures, cited a case in which hearing was improved by removal of the drum and ossicles.

Dr. J. E. NEUCOMB (New York), speaking of treatment by electrolysis, said that the younger practitioners in New York had used it and had recorded good results but the senior men had left this form of treatment alone.

Dr. W. JOBSON HORNE (London) expressed the hope that early steps would be taken to adopt Dr. Barr's suggestions for the scientific investigation of the subject they had been discussing. It was now half a century since Toynbee so largely contributed to their knowledge and Dr. Horne thought he was not over-stating the matter in adding that during that interval but little had been done by means of scientific research to advance their knowledge of the non-exudative or dry forms of ear disease. He was aware of the obvious difficulties, but one case completely worked out would be of greater help than a mass of empirical and experimental treatment.

The PRESIDENT, summing up the discussion, endorsed Dr. Barr's suggestions.

The openers of the discussion replied.

TROPICAL DISEASES.

WEDNESDAY, JULY 27TH.

The President of the section, Dr. ALEXANDER CROMBIE, C.B., Lieutenant-Colonel I.M.S. (retired), delivered an introductory address entitled

The Fallacy of Finality.

Referring to a paper on Indian Fevers which he had read at the Indian Medical Congress of 1894, Dr. Crombie stated that his attempt to differentiate certain fevers of the continued type had been freely criticised and he intended to refer to the subject again. Clinicians had been, on the whole, favourable to the view which he then took, but bacteriologists had been opposed to it. "Ague," according to Dr. Crombie, was not the most prevalent type of fever; according to his Indian experience the commonest type of fever was a "single paroxysm fever" of a few hours' or a few days' duration, but it was a single paroxysm and had no tendency to recur. If it lasted for a few hours only it was termed "ephemeral fever," if for a day or two "febricula," and if for several days "simple continued fever." In fever of this kind periodicity was wanting, the patients recovered without quinine, and malarial parasites were not present. Captain Leonard Rogers differed in this point, basing his argument upon mononuclear increase; but this increase had been shown to be present in other diseases besides malaria. An inquiry by Captain S. P. James led him to the conclusion that many cases admitted as malarial in Indian hospitals were not due to malaria, no malarial parasites being found in the blood. Mr. Arthur W. Powell bore similar testimony and it would seem that many of the cases of febricula and simple continued fever in India were non-malarial. The form of fever styled "non-malarial remittents" by Dr. Crombie and lasting in some cases six weeks was pronounced by the late Dr. Hughes and Dr. E. Charles to be Malta fever, but this contention had not been upheld. Kala-azar was also at one time thought to be Malta fever but this position had also proved false. At one stage of investigation it was held that every fever that was not malarial must be typhus, enteric, or Malta fever. The leucocyte count seemed quite recently in Captain Rogers's hands to settle the question and a fever showing an increase of the percentage of lymphocytes was held to indicate typhoid fever, and an increase of the large mononuclears malaria, but the increase of mononuclears had been found in blackwater fever, in the spotted fever of the Rocky Mountains, and in the fever associated with Leishman's bodies. In regard to non-malarial remittents being typhoid fever the laboratory evidence at their disposal consisted chiefly in the acceptation of Widal's reaction but this was a wholly inconclusive argument. A species of fever which ran a three or four weeks' course and was well known in India and which was usually asserted to be typhoid fever Dr. Crombie chose at one time to term "urban fever" as occurring for the most part in large towns; he was now inclined to regard it as a peculiar form of typhoid fever. There were several forms of enteric fever and to the India variety he would assign the name "bastard typhoid." The fallacy of finality was amply borne out and Dr. Crombie especially wished to sound a warning note concerning "the fallacy that every step made in advance is final, and that every part of medicine must be brought into line with it for the reason that there is nothing beyond."

Colonel **DAVID BRUCE**, F.R.S., R.A.M.C., opened the discussion on

Trypanosomiasis.

After referring to the state of knowledge at the meeting of the British Medical Association in 1903 and what they knew of trypanosomiasis and sleeping sickness now, Colonel Bruce stated that (1) the trypanosoma found in the blood of natives on the West Coast of Africa and in Uganda and those found in cases of sleeping sickness were identical; (2) the so-called trypanosoma fever was nothing but the first stage of sleeping sickness; (3) neither the native nor the European was immune to this disease; (4) the mortality in both coloured and uncoloured races was 100 per cent.; (5) up to the present no evidence had been brought forward to show that any of the lower animals took any important part in the spread of human trypanosomiasis; (6) human trypanosomiasis was conveyed from the sick to the healthy by means of a biting fly, the glossina palpalis; (7) several members of this genus were able to convey the virus from the sick to the healthy, thereby constituting a danger that this disease might spread into British East Africa and other tsetse fly zones; (8) there was no proof that other genera than glossina, such as stomoxys and tabanus, could convey this trypanosome; (9) there was no proof that trypanosoma Gambiense passed through any metamorphosis in glossina palpalis but that the transference of the parasites by this fly from one animal to another was purely mechanical; (10) all the stages of the development [illegible] the human host [illegible] words, that the [illegible] the intermediate host for its continuance; and (11) to prevent sleeping sickness the movement of natives from sleeping sickness areas into any part of the country where any species of tsetse fly was found should be prevented as far as possible, and, again, the movement of healthy natives into sleeping sickness areas should be prevented where possible.

Dr. **DAVID N. NABARRO** (London) said that after Colonel *Bruce left Uganda Captain E. D. W. Grieg and Dr. Nabarro* himself immunised several monkeys against the blood and the cerebro-spinal fluid trypanosoma and found that the animals were then immune against the cerebro-spinal and the blood trypanosoma respectively, though not against the animal trypanosomata met with in Uganda. In regard to the conclusion come to by Colonel Bruce that "so-called trypanosoma fever is the first stage of sleeping sickness," Dr. Nabarro did not think that they were quite justified in going so far nor did he think it would always prove to be the case. The trypanosoma might disappear altogether from the peripheral blood of a patient, as it did in some monkeys and dogs experimented on. Cases of sleeping sickness in the pyrexial or so-called first stage of the disease suffered from remittent or intermittent fever, but the converse could not be maintained with certainty—viz., that trypanosoma fever was always the first stage of sleeping sickness. Man might possibly become immune after infection with trypanosoma, as in the case of monkeys and dogs and other animals. Concerning infection by lower animals, Dr. Nabarro said that there was a disease amongst oxen in Entebbe in Uganda associated with a trypanosome which if not identical with, yet closely resembled, the human trypanosoma and it was just possible that these oxen might serve as a subsidiary host in addition to infected natives whence the glossina palpalis obtained its supply of trypanosoma. This trypanosome became very scanty in the blood of sick oxen towards the end of life and in one case could [illegible] even [illegible] of the [illegible] artificial inoculation although they did not suffer from undoubted sleeping sickness symptoms. Dissection of flies at varying intervals after a feed yielded interesting results which might be summarised as follows. The trypanosoma of sleeping sickness was actively motile in the stomach contents of the fly 71 hours after the feed; the trypanosoma found at Jinga lived 100 hours, the East African five and a [illegible] stomoxys [illegible] the East [illegible] l.

[illegible] r **DUTTON** (Birkenhead), and Dr. **JOHN L. TODD** communicated a paper on

Human Trypanosomiasis and its Relation to Congo Sleeping Sickness.

The paper was described as an abstract from the second progress report of the expedition of the Liverpool School of Tropical Medicine to the Congo, 1903. The full report was published in the Thompson-Yates and Johnston Laboratory Report for July, 1904. During the expedition the investigators found at the Leopoldville Hospital that out of 465 natives coming from all parts of the Upper Congo as well as the districts round Leopoldville 54 had trypanosomes in their blood. In the Gambia, on the other hand, out of 1043 natives examined six only were found with trypanosomes in their blood. Mild and severe types of sleeping sickness were met with but there was no well-defined demarcation between them, but for descriptive purpose they were grouped as (*A*) cases with no definite symptoms of illness; (*B*) cases with few symptoms; and (*C*) fatal cases showing well-marked symptoms, the most notable being fever, lassitude, weakness, and wasting. They subdivided group *C* into (*a*) fatal cases showing no sleep symptoms and (*b*) fatal cases showing sleep symptoms, and remarked that deep sleep, continued sleep, and lethargy—symptoms described as characteristic of sleeping sickness—were not features of the Congo disease. Although one epidemic of sleeping sickness was recorded in the Congo district they did not meet with an epidemic of the disease during their investigations. The Congo type of case bore a close resemblance to some of the cases described by Bruce, Greig, and Nabarro on the Victoria Nyanza after the epidemic wave had passed that region. Concerning secondary infections and complications it was found that secondary bacterial infections seemed to determine the fatal issue of many cases of Congo sleeping sickness; the complications or obvious secondary infections met with were purulent meningitis, purulent pleurisy and pneumonia, pneumonia and localised tubercle of the lung, localised gangrene of the lung, enlarged caseating and breaking-down glands in the thorax and abdomen (no tuberculous lesions in the organs—tubercle bacillus in glands was seen in one case), dysenteric ulceration of the large bowel (perforation in one case), universally adherent pericardium (recent), and infiltration of pus in femoral, inguinal, and intestinal iliac glands (gonorrhœa). These observations corresponded with the lesions described as met with in Uganda. The authors further remarked (*a*) upon the periodicity and frequency of recurrence of the parasites in the peripheral blood; (*b*) the number of parasites appearing in the blood—in two cases a large increase was noted to occur during the few days immediately preceding death; (*c*) the sudden disappearance of the parasite from the finger blood; (*d*) the symptoms associated with the increase of the parasites in the blood—a rise of temperature was not necessarily associated with an increase of parasites in the blood and the number or constant presence of the parasites in the peripheral blood would seem to bear no relation to the severity of the disease; (*e*) the occurrence of parasites in serous fluids—in hydrocele fluid parasites were found; (*f*) the occurrence of the parasites in tissues and fluids after death—parasites were found in the pericardial, pleural, and peritoneal fluids when examined fresh; (*g*) animal experiments—rats, mice, guinea-pigs, rabbits, and monkeys were injected with human trypanosomes taken from cases of Congo sleeping sickness, both in its early and its latest phases (no animals inoculated with material in which trypanosomes were seen, taken post mortem from cases of trypanosomiasis, have ever become infected); and (*h*) transmission experiments—both in the Congo and Gambia the guinea-pig was, perhaps, the laboratory animal most susceptible to trypanosoma Gambiense.

Dr. CHRISTY read a paper upon

The Cerebro-spinal Fluid in Sleeping Sickness (Trypanosomiasis),

being part of the second progress report of the expedition from the Liverpool School of Tropical Medicine to the Congo, 1903, and published in the Thompson-Yates and Johnston Laboratory Report, August, 1904. Dr. Christy stated that 104 lumbar punctures were made. Of 64 cases operated on 54 were proved to be cases of sleeping sickness by the discovery of trypanosomes in the blood, the cerebro-spinal fluid, or the hydrocele fluid. Of the 54, parasites were found in 34 of them sooner or later in the cerebro-spinal fluid. In the Congo disease there appeared to be an endless variety of types. In most cases sleep was absent, in some dulness and apathy were prominent, in others nervous symptoms and mania were conspicuous, while a proportion of cases had only progressive emaciation and fever. The presence of parasites in the cerebro-spinal fluid apparently led to increase the gravity of the case and predisposed to new complications. Dr. Christy described in detail the best method of performing lumbar puncture.

Sir PATRICK MANSON (London) stated that Colonel Bruce's contention that the trypanosoma Gambiense was the cause of sleeping sickness was founded principally on an epidemiological basis. Experimental evidence was wanting, inasmuch as the small-celled organism associated with the perivascular spaces of the brain in cases of death from sleeping sickness was not found after any infection of animals yet reported. Colonel Bruce's epidemiological facts applied to only a very limited region and, as in the case of the suspected filaria perstans, it might be proved that trypanosomes did not correspond in their distribution with that of sleeping sickness. Quite recently it had been stated that in the territory at the south end of the Victoria Nyanza the entire population was infected with trypanosomes but sleeping sickness was unknown there. If this be true then the trypanosoma could not be the only cause or even a cause of sleeping sickness. The trypanosome would appear to be an element in the causation but the determining cause of the pathogenic condition was bacterial. A combination of Castellani's first and last etiological views would therefore seem to be the correct one. Sir Patrick Manson mentioned the case of a patient in whom all the clinical symptoms of trypanosomiasis were present and in whom trypanosomes were found in the blood who was now quite well, although it was three years since the illness declared itself.

Dr. LOUIS SAMBON (Naples) remarked that he could not regard the glossina to be merely a mechanical carrier of the disease trypanosomiasis. If this were so, how was it that other biting insects, such as the stomoxys and the tabanus, did not also convey the disease? The glossina would seem to be the intermediate host of the parasite.

Mr. H. F. CONYNGHAM (demonstrator at the London School of Tropical Medicine) read a paper entitled

A New Trematode of Man (Amphistomum Watsoni).

Mr. C. F. Watson sent to the London School of Tropical Medicine from North Nigeria six trematodes from the small intestine of a negro who had died from starvation and diarrhœa. This proved to be a species of amphistome totally unlike the gastrodiscus hominis (Lewis). Professor Blanchard of Paris had pronounced the trematode to be a new species. Post mortem the parasites were found in the duodenum and upper part of the jejunum and a few had reached the large intestine. The man was reported to be fond of raw meat. The animals were pear-shaped, flattened ventrally, and indented posteriorly at the margin of the posterior sucker. The anterior sucker was terminal and ventral. The genital pore lay about a quarter of the length of the parasite from the anterior end. The cuticle was ribbed transversely, especially on the ventral surface. The worms measured eight millimetres in length and five millimetres at the point of greatest breadth; the greatest thickness was about four millimetres. Ova as seen in the uterus measured 130μ by 75μ. The parasite was found in enormous numbers in the upper part of the small intestine and might have been the cause of death seeing that in some of the lower animals serious illnesses were occasioned by other species of the same genus.

Captain LEONARD ROGERS, I.M.S., contributed a paper on

The Treatment of Snake Bites.

The class of colubrine (including the sea snakes hydro-ophidæ) by their venom killed by paralysing the respiratory centres and to a less extent the motor end plates of especially the phrenics. The viperine class (including true vipers) caused by their venom a rapid failure of the circulation due to paralysis of the central vaso-motor centre in the medulla. Calmette's antivenin serum was only active against colubrine venoms. Experiments with the antivenin made by Burroughs, Wellcome, and Co. from cobra venom showed that when given subcutaneously it had little or no effect, but when given intravenously it acted well. Captain Rogers described the local treatment with permanganate of potassium. In his experiments he ligatured the limb above the seat of injection of the venom, an incision was then made into the seat of the injection, and solid crystals of permanganate of potassium were rubbed into the spot with sterile salt solution. Recoveries were the rule when the ligature was quickly applied above the part bitten and the lethal dose was not too large. This beneficient result was obtained in both colubrine and viperine poisons. The local use of the permanganate with, in the case of colubrine poison, antivenin injected intravenously, and in the case of viperine poison by adrenal extract injected subcutaneously, would appear to be encouraging methods of treating snake poisons.

Mr. ERNEST E. AUSTEN (Zoological Department of the British Museum) read a paper entitled

Supplementary Notes on the Tsetse Flies (Genus Glossina, Wiedemann).

In addition to the seven species of tsetse flies already known an eighth species had recently been described and named glossina Decorsei (Brumpt). The new species was obtained by Dr. Decorse from the banks of the River Shari and the shores of Lake Chad. It was believed that nagana was carried by five of these species. Mr. Austen described glossina palpalis, glossina pallicera, glossina morsitans, glossina tachinoides, glossina pallidipes, glossina longipalpis, glossina fusca, and glossina longipennis. Mr. Austen believed that, in addition to trypanosomiasis in its various forms, tsetse flies must play an important part in the dissemination of other diseases due to hæmatozoa. Brumpt stated that in certain districts on the Upper Congo a filariasis due to filaria volvulus was very widely spread; the disease occurred only among the canoe-paddlers—*i.e.*, among those who were most exposed to the bites of tsetse flies—and Brumpt wrote that the only cases hitherto observed had been in the regions (such as Nigeria and Dahomey) in which tsetse fly abounded.

Dr. CHRISTY, Dr. DUTTON, and Dr. TODD communicated a paper on

The Congo Floor Maggot, a Blood-sucking Dipterous Larva found in the Congo Free State.

This contribution was part of the report of the expedition from the Liverpool School of Tropical Medicine to the Congo, 1903. These maggots lived in the dust-filled cracks and crevices of the mud floors of native huts in the cataract regions of the Congo. Many of the larvæ found contained bright-red blood and they were most numerous where the natives slept on floor mats and there seemed no doubt that they bite at night. These larvæ were found at Leopoldville all over the Luteto and surrounding districts and they were reported from San Salvador in Portuguese territory, on the Congo at Matadi in the cataract region, and at Johumbiri, 150 miles above Stanley Pool. The flies met with in the huts and supposed to be developed from the floor maggots were submitted to Mr. Austen of the British Museum who recognised them as specimens of *Auchmeronigia luteola* Fabr (a species of the family muscidæ). The relationship of the floor maggot to the Auchmeronigia luteola had not been established and the possibility of the maggot being a means of diffusing trypanosomiasis was merely suggested.

Mr. T. J. TONKIN (Yapton) remarked that in the town of Kano in Northern Nigeria his servant proceeded to clear out the cracks on the part of the floor on which he was about to spread his sleeping mat. The reason for this precaution he was told was because a biting insect lived in the cracks and a specimen was shown him which in all points resembled that described by Dr. Christy.

Dr. D. E. ANDERSON (Paris) also took part in the discussion.

DENTAL SURGERY.

WEDNESDAY, JULY 27TH.

Mr. E. A. BEVERS (Mayor of Oxford) read

The Presidential Address.

He congratulated his dental colleagues on obtaining a dental section at the annual meeting of the Association. He referred to the progress which dental surgery had made—progress which on the whole had been slow but sure but which had every now and then been marked by distinct advances, one of which he considered they were taking part in that day, because by the formation of that section dentistry had taken its proper place in the fold of medicine. The influence of the section would be to encourage a broadening of their views and also to permit medical men to know more about the aims and claims of dentistry. Reference was made to the divergent views which were held on the question of education and an appeal was made to support those who believed in broadening the general portion of the curriculum. The claims made by American dentistry he ridiculed and pointed out that dentistry was catholic—the science was the same in whatever country it was practised—and that there could therefore be no such thing as a system special to one country.

Dr. W. HUNTER (London) opened a discussion on

Oral Sepsis in Relation to Disease.

He referred to the interest that he had taken in the subject, especially in relation to pernicious anæmia. Medical men took infinite precautions to protect the body against pyogenic affections but neglected the mouth as a source of infection. He was happy, however, to note that increasing attention was now being given to the subject. Much, however, remained to be done, as even in the most recent text-books no mention could be found of the influence of morbid conditions of the teeth and adjacent tissues on general health. The main trouble arose not so much from the presence of carious cavities in the teeth as from suppurative conditions of the periodontal membrane. Of the local effects of oral sepsis the first to claim attention were gingivitis and the various forms of stomatitis. Tonsillitis, too, he had found to be most severe in type when associated with septic teeth; and in his opinion in cases of throat affections occurring in scarlet fever patients a septic state of the mouth very considerably aggravated the throat trouble. Adenitis was frequently associated with carious teeth, as were otitis media, naso-pharyngeal [illegible] disease. Passing to the stomach, he [illegible] cases of septic gastritis due to streptococcal infection in which there was the foulest oral sepsis. A similar condition of the mouth he had met with in cases of septic enteritis and ulcerative colitis. In cases of typhoid fever he had performed 50 post-mortem examinations where perforation had occurred and he was of opinion that the perforation was always due to some superadded inflammation and more than possibly traceable to infection from the mouth. He thought there was reason to believe that oral sepsis was at times the focus of infection in cases of malignant endocarditis, purpuric hæmorrhage, and nephritis. Two distinct types of anæmia he had found associated with oral sepsis: (1) septic anæmia, in which there was an absence of hæmolysis, and (2) pernicious anæmia, in which there was marked hæmolysis accompanied by intense bone-marrow changes.

Mr. KENNETH W. GOADBY (London) read a short note on

The Pathology of Oral Sepsis.

Oral sepsis, he said, was a very wide term and embraced such different conditions as ordinary dental disease and a generalised stomatitis of whatsoever cause. It was therefore essential to make some sort of selection and the particular chronic diseases of the alveolus had been selected. Three chief varieties of this particular section of oral pathology might be cited as having certain clinical signs as well as some difference in their bacteriology, which allowed a preliminary classification. They were: 1. Gingivitis. This was a general or local inflammation of the margins of the gums about the teeth, not involving the alveolus or alveolar-dental periosteum. This condition was accompanied by some smell of the breath, but little or no pain. 2. Progressive periodontitis. This was a chronic inflammation of the whole of the gum and mucous membrane covering the alveolus or an atrophic condition with atrophy of the tooth sockets. There were formation of distinct gum-pockets and infection of the alveolar-dental periosteum, without definite affection of the alveolus itself, accompanied by considerable quantities of pus, either thin and filled with débris or thick and viscous. There were usually a sweetish smell of the breath and infection of the mucou glands on the inner surface of the cheek at points corresponding to the greatest amount of inflammation; there was frequently localised as well as general neuralgic pain. 3. Subacute alveolar osteitis. This was a well-marked infection of the bone in the form of rarefying osteitis often spreading to the antrum, with much granulation tissue in the sockets of the teeth and deposits of semi-cartilaginous nature on the roots of the teeth; pain was common; there was frequent exacerbation of disease around individual teeth with dento-alveolar abscess. Sinuses formed, running into the compact bone. They were often associated with chronic pharyngitis and other throat diseases. The bacteriology of the disease was as follows: 1. Gingivitis. The largest variety of bacteria were found in this condition; almost all morphological forms were to be seen on making coverslip preparations. The following might be noted: staphylococci, sarcinæ, spirilla, comma-shaped bacilli, long curved rods, short thick bacilli, long pointed bacilli, and fine threads. 2. Progressive periodontitis. (*a*) Rods 4μ to 6μ long, 0·75μ wide, associated in masses. (*b*) Threads 10μ to 20μ long, many showing a beaded appearance, with large, darkly-stained d[illegible]illus by Neisser. [illegible] thicker and stained with [illegible] egularly twisted filaments, with occasional branching. (*d*) Thick-jointed rods, sometimes giving granulose reaction. Cocci were generally found but the spirilla and comma-shaped forms, with the exception of spirochætal, were reduced in numbers. 3. Subacute alveolar osteitis. (*a*) Generally appearance of fragmented mycelium, which might stain by Gram's method. (*b*) Thick bacilli with pointed ends, the bases of the two being in apposition, not unlike gigantic sheath-forms of diphtheria bacillus. (*c*) Bacilli of diphtheria-like form (short), associated with cocci in the depths of the sockets of the teeth. Comma and spirillum forms were generally absent in this last process; although they were often increased in various forms of stomatitis they were not related to any one condition. They might be found in the throat in diphtheria, enteric fever, &c. The recent suggestion of Wright that these spirilla were a variety of trypanosome, on account of their staining reaction, was inadmissible; other bacteria also stained in the same way with the reagents used. It was thought that by inoculating pus obtained from the above diseases directly into animals some idea of the pathogenic organisms present (if any) would be obtained. The animals were inoculated subcutaneously, intraperitoneally, and intravenously. The results of these experiments were given as a preliminary report. One of the cases scheduled above was a case of pemphigus associated with acute oral sepsis. A pure culture of a bacillus was obtained from the blood drawn from the right median basilic vein. A similar bacillus was isolated from the mouth. The curious slow tissue necrosis found in some of the animals inoculated was interesting in view of the incidence of healed gastric ulcer, especially as Hemmeter remarked that "in gastric ulcer there is another kind of infection which is not accompanied by the signs of acute inflammation and is termed bacterial necrosis by some authors." The fact that many cases of oral sepsis rapidly improved with the improvement of some general disease—such, for instance, as the oral inflammation present in sprue—did not preclude by any means the mouth disease from sharing in the production of the other symptoms. It was difficult perhaps to understand the marked degree of immunity possessed by many individuals against oral sepsis, but yet many of these did ultimately exhibit evidences of chronic toxæmia; at the same time, it was difficult also to explain the mechanism of relapse in acute fevers, as well as accidental death during active immunisation of animals, with the modern conceptions of immunity. It might be concluded from a general survey of the facts touched upon (1) that a certain degree of virulence might be possessed by an organism living an apparently saprophytic existence in the mouth; (2) that inflammatory conditions had the effect of increasing the number of species as well as the total number of bacteria present; (3) that a sort of selection apparently took place but whether due to symbiosis or not it was difficult to say; (4) that mouth bacteria did at times gain access to the general blood stream; and (5) that finally the potentiality for disease of oral sepsis received considerable support from even a preliminary survey of its bacteria, perhaps pointing to its operation in even a wider rôle than was at present credited or admitted.

Mr. RICKMAN J. GODLEE (London) read a short paper on

Oral Sepsis in Relation to Surgery.

He considered it would be interesting to investigate the direct effect of toxic matter from the mouth on wounds. There was every chance of surgeons with septic conditions of the mouth infecting patients, as in the act of speaking a slight expectoration of saliva was often unavoidable. He would therefore say to surgeons, examine your mouth for the sake of your patients. The presence of oral sepsis in domestic animals was overlooked and he characterised the habit of kissing dogs as dangerous. The improvement in the results of operation on the mouth was to be attributed largely to the care now taken to render the mouth as aseptic as possible before operating and he impressed on all surgeons the necessity for carrying out this mouth hygiene. Tuberculous glands were often traceable to septic teeth and although there was a disposition on the part of some dental surgeons to retain a suspicious tooth from an æsthetic point of view, he thought that all such teeth should be removed, for a beautiful jaw was not much good if it surmounted a scarred neck. Reference was made to the severe condition occasionally following dento-alveolar abscess and a case was cited of extensive necrosis of the mandible following the removal of a molar tooth. In all operations on the alimentary track the mouth should be submitted to rigid treatment previously to operation.

Dr. DALTON spoke of some cases of malignant anæmia he had met with associated with oral sepsis. He discussed the question whether the anæmia was due to the sepsis or *vice versâ* under three heads: (1) priority of oral sepsis or anæmia; (2) whether the anæmia passed away with removal of the teeth; and (3) why septic mouths produced anæmia and similar conditions of the pleura and other cavities did not. He seemed to incline to the view that the anæmia was traceable, at any rate in some cases, to the oral sepsis.

Dr. STCLAIR THOMSON (London) said that he always refused to operate on the throat until the nose and teeth had been placed in order. With reference to the amount of pus that was swallowed in cases of oral sepsis he thought an idea could be gained from a case recently under his care. He operated for suppurative tonsillitis. The patient was properly prepared for operation; no blood was swallowed but vomiting took place from the anæsthetic and two tablespoonfuls of pus were brought up. This must have been swallowed during the night, roughly a period of 12 hours.

Dr. HERBERT TILLEY (London) quoted two cases of severe mental depression in which the symptoms completely disappeared after the treatment of antral suppuration.

Mr. J. G. TURNER (London) approached the question from a clinical point of view. He remarked on the extreme frequency of the condition and said that early stages were often overlooked. It was not an easy thing to treat such a condition and no mouth could be considered healthy until every pocket was free from suppuration. With regard to the question of immunity to the results of oral sepsis he thought that the absorption of small doses produced an acquired immunity but that was not health; such a condition could not last and sooner or later a complete breakdown occurred. A case lately under his care illustrated this point. With regard to the local immunity the granulation tissue in the sockets resisted the invasion of the organisms but if that tissue were injured infection followed. Clinical experience, he thought, pointed that way.

Mr. NORMAN BENNETT (London) spoke of a case in which a girl, aged 16 years, had been the subject of fainting fits. The attacks varied in frequency, at times several occurring in a day; they took the form of unconsciousness, with rigidity, groaning, and movements of the limbs. The septic condition of her mouth was treated and the fainting attacks ceased. The cases pointed, he thought, to an obscure general condition arising from the local mouth lesion.

Dr. GOODALL (London), Professor J. ARKOVY (Budapest), Mr. E. LLOYD-WILLIAMS (London), and Mr. W. HERN (London) also took part in the discussion.

THURSDAY, JULY 28TH.

Mr. J. ACKLAND read for Mr. W. H. BATTLE (London) a short account of

A Case of Melanotic Alveolar Sarcoma

of the anterior part of the maxilla in a child, three months of age. The tumour was removed in July, 1902, and now (July, 1904) the patient was quite free from recurrence.

Professor ARKVOY read a paper on

Caries Alveolaris Specifica or Pyorrhœa Alveolaris.

He referred to one special form. The alveolar condition was accompanied by abscesses which were cavities larger than the usual circumscribed abscess and contained often no pus. Fever might be present, lasting for a week if pus was present, though if present it was only in small quantities. The pulp of the teeth might be alive but was inflamed. The pyorrhœic process was at times so acute that all the teeth were loosened in a few weeks. There were also "uratic blisters" on the gums but these were not products of acute sepsis but probably gouty.

Mr. TURNER had seen the large abscesses in their chronic state but not the complexity of symptoms described by Professor Arkövy.

Mr. P. SYDNEY SPOKES (London) asked if the uratic blisters were not analogous to chalk-stones.

Mr. GOADBY knew the abscesses and described one which led to thrombosis of the facial vein and death. He thought the acute [illegible] was due to superinfection and symbiosis inducing [illegible] virulence.

Mr. W. [illegible] (London) thought the pain a constitutional dist[illegible] and unilateral distribution pointed to the uratic blisters being herpetic.

Mr. SPOKES read a paper on

The Care of Children's Mouths.

The examination of 10,000 school children of an average age of 12 years showed that only 15 per cent. had sound teeth and it was safe to say that decay of the teeth occurred to a larger extent than any other departure from the normal physiological standard. It was difficult not to believe that the condition met with in a systematic examination of the mouths of such children, as yet untreated, must have some prejudicial effect, and that it resulted in a lower nutrition than might be otherwise attained if the teeth were sound and mastication was thoroughly performed. A large proportion of such children were not able to deal with food efficiently, either from actual loss of masticating surfaces or because of tenderness or actual pain upon pressure. Again, when a child was attacked by some infective or constitutional disease was it not reasonable to suppose that the resistance of the organism might be greater had nutrition, aided by thorough mastication and insalivation, been maintained at its highest possible level? Further, there appeared reason to think that the mouth itself with broken-down teeth and septic pulp chambers might be the spot in which the infective material was cultivated, and that whereas in a healthy mouth pathogenic organisms might meet with a peaceful end, in the diseased mouth propagation was provided for and a larger dose was prepared for entrance to the body by the lungs, stomach, or lymphatics. At the least they might say that any departure from the normal was a matter of significance and that septic [illegible] ing cause of other diseases. [illegible] times a year with dental [illegible] life. If commencing decay was found it should be promptly dealt with by "stopping" and at such a stage this could be done with a minimum amount of trouble to both patient and operator. The teeth of the deciduous series should be preserved in this way until their successors were ready to take their place. But when, on examination, it was found that deciduous teeth had been allowed to decay so far as to become necrosed and septic they should be removed in order to secure a healthy mouth.

Mr. TURNER read a paper on

The Influence of the Growth of Bone on the Positions of the Teeth.

Too little attention was paid to the influence of the growth of bone in producing the normal arrangement of the dental arch. The six front teeth, both permanent and deciduous, though developed in a definite but crowded arrangement, eventually took up positions in a regular arch. The three permanent molars developed one after the other—the upper with their occluding surfaces facing backwards, the lower forwards and upwards; all eventually assumed vertical positions in the dental arch. The anterior deciduous teeth, at first in apposition, by about the end of the fifth year are separated by as much as one-eighth of an inch. All these movements were due to growth of bone which carried the teeth with it. When, as in naso-pharyngeal obstruction with adenoids, growth was arrested or delayed, the teeth also failed to get moved into their normal positions. Models illustrating these cases showed that in children the normal spacing of the front teeth failed; that the permanent molars were erupted in too narrow an arch, while if the obstruction were removed or "outgrown" the molar next erupted came in a wider arch, due to increased lateral growth of the maxilla, but the parts in front were left in their deformed state, since the time for their growth had passed; and that "open bite" was in some cases due to deficient vertical growth of the anterior part of the maxilla. The front teeth were often found fixed in a more or less fœtal position, recalling the crowded position of development. All these deformities were easily explained as due to arrested or delayed growth of bone. Examples of unrestrained growth of bone were seen in the way in which a second maxillary molar moved forward after extraction of a first permanent molar and a second mandibular præmolar *backward* after extraction of the lower first molar. Deformities of the dental arch were valuable indications of deficient growth of the maxilla and adenoids might often be suspected, especially when in children the deciduous front teeth failed to "space" themselves.

In the discussion which followed Mr. H. BALDWIN (London), Dr. J. SIM WALLACE (London), and Mr. W. A. MAGGS took part.

Dr. WALLACE read a paper on

The Teeth in Relation to Physical Degeneration.

Attention was given to a consideration of the harmful effects of diseased states of the teeth on general physical development, but still greater stress was laid on the present-day craze for feeding children with highly refined assimilable and soft foods. Dr. Wallace enforced his arguments by referring to the fact that, notwithstanding general amelioration on account of improved sanitation, &c., these very [illegible] ritious pap system of [illegible]. Under this category [illegible] stion, constipation, and consequent fermentation of food in the intestine often leading to fatal diarrhœa, appendicitis, neurasthenia, adenoids, anæmia, and rickets. He insisted on the fact that the alimentary canal had through countless generations become adapted for the extraction of nutriment from relatively innutritious matter, while the present-day belief "would appear to be to take in nutriment at the mouth and by the aid of pills render the intestine capable of extracting excrement from it." He considered that food should be of such consistency as to stimulate mastication and should contain sufficient innutritious matter to cause regular daily evacuation of the bowel. For this purpose he advocated the products of the kitchen garden and orchard rather than the products of pastry cooks, confectioners, and proprietary food manufacturers.

THE NATURE AND ETIOLOGY OF CANCER.

At the conversazione given by the Vice-Chancellor and the members of the University two interesting demonstrations with regard to the nature and etiology of cancer were given, the first by Mr. C. E. WALKER and the second by Dr. W. FORD ROBERTSON and Mr. H. WADE. Both demonstrations were illustrated by lantern slides.

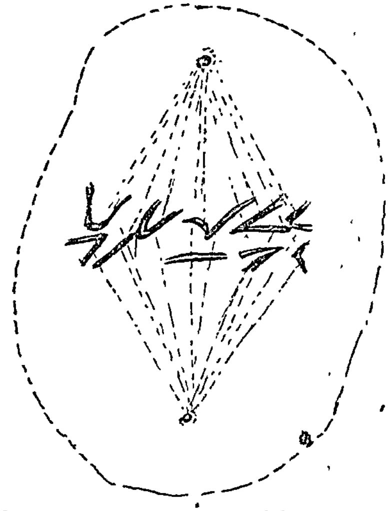
(1) MALIGNANT GROWTHS IN MAN AND NORMAL REPRODUCTIVE TISSUES.

Mr. WALKER dealt with the researches carried out by himself in conjunction with Professor J. B. Farmer and Mr. J. E. S. Moore, the results of which were communicated to the Royal Society on Dec. 10th, 1903, and the main points of which were published in THE LANCET of Dec. 26th, 1903, p. 1830. Mr. Walker recapitulated these points as follows:—

The Methods of Division of Somatic and of Reproductive Tissue Cells.

The value of the deductions to be made depended to a great extent upon the differences between the manner in which the somatic cells—the cells forming the ordinary tissues of the body—and those which were destined to form reproductive tissue divided. To emphasise the similarity existing between malignant tissue and the normal tissues of the sexual reproductive glands it was proposed to introduce the term "gametoid" to express the former and "gametogenic" the latter. When the egg of an animal or plant segmented so as to give rise to an organism the nuclei of all the cells were found, when dividing, to contain a definite number of rod-like bodies known as chromosomes, this number remaining constant throughout subsequent divisions. Besides remaining constant in number, however, the

FIG. 1.



[illegible]

chromosomes passed through a very definite series of evolutionary changes. At first the material out of which the chromosomes originated appeared as granules of stainable substance (chromatin). Then, after certain characteristic stages, this substance took the form of chromosomes, of which the number proper to each animal or plant was constant. During the process of division each of these chromosomes split longitudinally into two daughter chromosomes which at that period were arranged in a very definite manner upon the spindle, frequently appearing as V's with the apices towards its axis (Fig. 1). The daughter nuclei were formed by the distribution to either pole of the spindle of the respective halves of each original chromosome. The nuclei thus formed might now enter upon a period of rest. Whenever new *somatic* cells were formed in the body the nuclei passed through identically similar phases. But in every individual there were certain cells which eventually gave rise to the gametogenic elements, not to the specialised somatic tissues. Such cells, whether they appeared early in embryonic life, or later during the life of the individual, always presented very marked difference in their mode of division and in their subsequent history. These differences first became apparent as the cell commenced its preparation for division. Those cells which were about to produce the gametogenic elements presented a highly peculiar appearance, and at a definite stage in the multiplication passed through a cycle of changes wholly different from that passed through by the cells of the surrounding tissue and also from the changes occurring in those cells from which they themselves had sprung.

To the particular form of division (mitosis) associated with this metamorphosis the term "heterotype" had been applied and it was a characteristic and interpolated stage in the reproductive cycle of all sexually propagating animals and plants. Cells from which the heterotypically dividing elements would finally emerge could often be distinguished from those which would produce somatic tissues. In the testis of a mammal or in the sporogenous tissue of a stamen the existence of these cells might be recognised with ease and certainty. They continued to multiply and though differing from the adjacent cells in many respects resembled them in their mode of division until they passed severally into that peculiar state of growth that ushered in the heterotype division. The essential features in which this heterotype mitosis differed from the somatic mitosis (that of the cells forming the soma or body of the plant or animal), as well as from those in the cell generations of the reproductive tissues that had preceded it, were as follows: 1. A period of rest and growth. 2. The chromosomes when they were formed from the resting nucleus were present in only half the number of those occurring in the rest of the dividing nuclei of the organism. 3. The forms exhibited by the chromosomes were strikingly different from those of other nuclei. They presented figures resembling loops, rings, aggregations of four beads, and so on. 4. They were arranged longitudinally upon the spindle. Their division on the spindle was apparently always transverse aad not longitudinal, for even in examples where the separation might be interpreted as longitudinal fission the process as actually passed through differed markedly from the ordinary longitudinal fission exhibited by the chromosomes of every other mitosis. It would thus be seen that the heterotype mitosis was an easily recognisable phase in the history of the development of the gametogenic cells.

It was a fact of the highest inportance that when once heterotype division had supervened all the descendants of that cell in normal cases retained the reduced number of chromosomes, the cycle closing with the formation of the definite sexual cells. It was on the fusion of two of these cells (ovum and spermatozoon) that the double number of chromosomes was restored, and this number was characteristic of the fertilised egg and of all the cells to which it gave rise until the heterotype mitosis again supervened in the gametogenic tissues.

The Resemblances between the Growth of Malignant Tissue Cells in Man and those of Reproductive Tissue.

A systematic investigation of the cytological features of malignant growths in man had revealed the existence of a surprising degree of similarity between the phases that characteristically recurred in these growths and the transformations from somatic into reproductive cells as just described. Thus in a typical example of epithelioma they found that in the early stages of proliferation of the Malpighian layer the cells of the invading tissue at first passed through a cycle of somatic divisions, exactly as occurred during the early stages of the formation of normal gametogenic tissue. As cell multiplication proceeded, however, a change passed over the cells themselves. The protoplasmic continuity, to which their "prickly" character was due, became obliterated and the cells assumed that appearance of indifferent germ tissue so well known as a feature of the elements of which malignant growths were largely made up. Besides this a varying number of cells were observed, often situated in an ill-defined zone behind the growing edge of the advancing neoplasm, which had attained somewhat large dimensions. Each contained a nucleus which had grown to a considerable size. In those which had entered upon a prophase of division it was recognised that the chromosomes instead of appearing as delicate thin rods or V's split longitudinally, presented the appearance of short, thickened loops or rings, closely resembling the later prophase stages of the heterotype mitosis in the normal gametogenic tissues. Still more significant was the fact that in these cells the number of the chromosomes was obviously less than in the normal somatic cells or the surrounding tissues. In many cases it was determined that the numbers were approximately halved; and furthermore, it was clear that the loops and rings characteristic of this stage of the cellular development of malignant growths were arranged lengthways on the spindle and so were ultimately divided transversely, exactly as in the corresponding heterotype mitosis of the reproductive elements. Subsequent divisions appeared to resemble the somatic form but retained the reduced number of chromosomes (homotype division). The cells were in no *sense embryonic in character*, though they had so frequently been described as such in the past. Embryonic cells had the potentiality of the full normal number of chromosomes and exhibited them when in process of division. It was thus pointed out that in a most important respect the various malignant tumours presented certain common features, and that these features were similar to those observed in the normal process of differentiation of reproductive cells. They felt themselves justified in deliberately correlating the appearance of these malignant growths with the result of a stimulus which had changed the course of somatic cell development into that characteristic of gametogenic tissue. They looked upon this transformation as representing the immediate cause of the malignancy of the

FIG. 2.

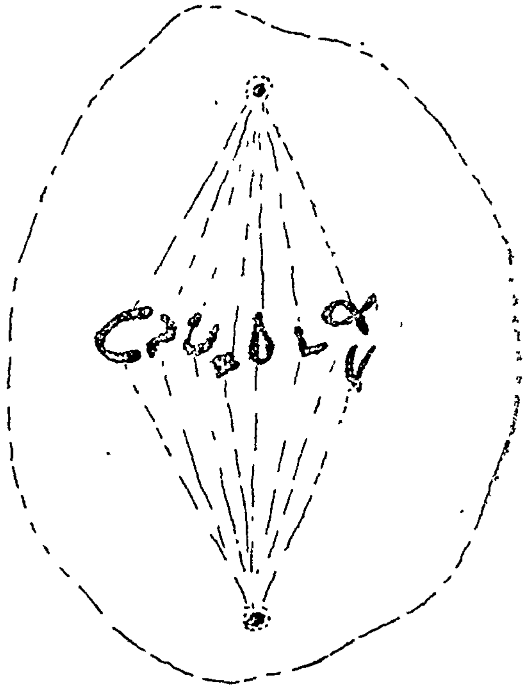


Diagram of a heterotypical division, showing the characteristic rings and loops which split transversely to form the daughter elements As in the former figure the full number of chromosomes is not shown.

growths in which they were found. The remote causes *must be sought amongst those various physiological stimuli*—occasioned, e.g., by continual irritation—*known to favour* their development. They also considered that malignant growths were definitely distinguishable from benign tumours, for in the latter they had not succeeded in discovering anything resembling the very characteristic nuclear changes described above.

Dr. W. FORD ROBERTSON and Mr. HENRY WADE showed *microscopical preparations illustrating some of* the results of an investigation into the Etiology of Carcinoma, carried out chiefly with the aid of metallic histological methods.

(2) CANCER AND PLASMODIOPHORÆ.

History and Technology.

Dr. Robertson said that they had undertaken the investigation with the object of testing the hypothesis, so strongly advocated by Roswel Park, Gaylord, and others in America, that carcinomatous tumours were due to the presence of an organism of the same nature as the plasmodiophora brassicæ, which was known to be the cause of certain tumours occurring especially in cruciferous plants. These vegetable tumours were commonly referred to as "finger and toe disease," "club-root," or "kohlhernie." Their own observations seemed to prove that minute plasmodiophoræ were indeed present in carcinomatous tumours and that they could be grown from such tumours through a definite *stage in their life cycle. The plasmodiophora brassicæ* had been first described by Woronin in 1878. The account of its developmental cycle which he had then given remained, with *unimportant modifications*, the one that was still accepted as accurate. According to this description the organism in the spore stage fell into the ground with the *decay of the plant which formed its host* and lay dormant until the spring or early summer. From each spore there then developed an amœboid swarm cell which might *find its* way *along* the root hairs of a *young* plant into certain cells. Here it multiplied rapidly and at the same time induced excessive proliferation of the cells in which it [illegible] l of the amœboid cells united to [illegible] nd within this spores were de[illegible] were extremely difficult to stain [illegible] ry histological methods were practically useless for the purpose of revealing their presence. They had found that certain metallic processes, more particularly the [illegible] *ning with* gold (see *Re*[illegible] ly, 1904), were speciall[illegible] organism in the vegetable tumours.

The Life Cycle of the Parasite.

With the aid chiefly of these methods they had been able to [illegible] the *developmental* cy[illegible] l apparently passed un[illegible] ative stage which oc[illegible] the spore and prese[illegible] place between the sp[illegible] *everal phases.* The recognition of the existence of these two stages was of the utmost importance for the investigation they had undertaken because the first was evidently the one in which the organism chiefly stimulated the cells of the host to abnormal proliferation, whilst the second was the only one through which the [illegible] be grown in culture media. Ha[illegible] referred to been aware of the [illegible] would probably by this time have established the accuracy of their hypothesis. A pre-spore, spore, pre-amœboid, amœboid or swarm cell, and a *plasmodial* stage were recognised. In the first phase of the pre-spore stage the organism in the silver-gold preparations had a prominent nucleus and a faintly coloured delicate cell-body, *limited* in optical section by a thin line. In the second phase the organism had increased slightly in size and assumed a round form; the nucleus was less prominent. This phase of the *pre-spore* stage passed gradually into the spore which appeared in the silver-gold preparations as a hyaline sphere, frequently presenting a central crimson spot. This was evidently the form in which the organism lay dormant in the ground during the winter. The immediately succeeding pre-amœboid phases had been observed in a vegetable tumour that had been incubated. The hyaline spore became granular and a central nuclear body made its appearance. This granular spore, as seen lying in the cell of the host, was *surrounded at some little distance by a delicate capsule* formed from the *surrounding tissues.* The granules gradually increased in size until they took the form of a number of *bodies resembling micrococci or short bacilli.* These further enlarged into spherical bodies with a sharply defined border. They proliferated rapidly and still further *increased in size. The development could not be traced* beyond this point in the incubated vegetable tumour, but the observations of Woronin, Gaylord, and others justified the *conclusion that these spherical bodies* ultimately became the amœboid swarm cells.

Similar Bodies found in Carcinoma.

In carcinomata they had been able to observe bodies which, in their form and in their reaction to the metallic processes employed, were identical with the plasmodiophora brassicæ in its pre-spore, spore, pre-amœboid, and amœboid stages. They differed from the plasmodiophora brassicæ only in being from one-tenth to one-twentieth of the size. They also appeared le[illegible] could be accounted for by the [illegible] tion of the animal cells. Th[illegible] pre-spore forms occurred chiefly in the protoplasm of the *epithelial cells. The spores were mainly, but not exclusively,* intra-nuclear. In their hyaline phase they could not be distinguished from a nucleolus, but when the granular phase was reached they could be shown to have characters identical with those of the granular spore of the plasmodiophora *brassicæ. The capsule derived from the cell in which the* parasite lay was, however, comparatively very thick and tended to obscure the body lying within it. Appearances which *seemed accurately to represent the escape of the* swollen and granular germinating spores from the nuclei and their subsequent development into large granules and *spherical bodies with sharply defined border could be traced* with little difficulty. Bodies having the same appearance as the amœbæ of the plasmodiophora brassicæ figured by Woronin could also be observed. They had succeeded in growing from carcinomata an organism having the characters of a plasmodiophora in its immediately post-spore phases. They could not speak definitely regarding the presence in carcinomata of bodies representing a plas[illegible] et had an opportunity [illegible] with the aid of their [illegible] g the known plasmodia with certain forms in carcinomata which were probably of a *similar nature.*

Conclusions.

Summarising their results and conclusions Dr. Robertson said that they had been able to recognise in carcinomatous tumours bodies which in their form and in their reaction to the platinum and silver-gold methods were identical with the plasmodiophora brassicæ, but from one-tenth to one-twentieth of the size. They had succeeded in growing from three carcinomata an organism which accurately represented the post-spore or pre-amœboid stage of a plasmodiophora. If plasmodiophoræ were present in carcinomatous tumours it was hardly open to doubt that they had the same relation to the morbid growth as the plasmodiophora brassicæ had to club-root—that was to say, *that they were the determining* etiological factor.

THE ANNUAL EXHIBITION.

V.—MINERAL WATERS, BEVERAGES, ETC.

There was a fair representation of mineral waters and beverages, and amongst them a few novelties. Perrier water, for example, though well known on the continent, has *only been recently introduced into this country. The water* is drawn from a spring situated in the Midi of France. *The* spring has been known from classical times. Perrier is an alkaline *water containing* chiefly lime salts with small quantities of sodium salts. The total saline residue is, however, small, amounting to less than 30 grains per gallon. The water has a very agreeable taste and is charged with its own natural carbonic acid gas. Messrs. Idris and Co., Limited, of Camden Town, London, N.W., exhibited a number of interesting aerated waters, including artifici[illegible] "distilidris," a distilled water [illegible] as carbonic acid gas; and "[illegible] ter containing certain salines [illegible] should be noted that the syphons are constructed with solid earthenware spouts so that the water does not come into contact at any point with metallic fittings. Amongst the largest displays of natural mineral waters was that of the Apollinaris Company, Limited, of 4, Stratford-place, Oxford-street, London, W. A feature of the display was Apollinaris water contained in large stone jugs holding nearly a quart of water. The exhibit included Johannis lithia water and Johannis potash water and Apenta, the magnesian bitter water from Buda-Pesth. Messrs. Allsopps, of Burton-on-Trent, exhibited specimens of their lager beer which is brewed on the continental system. It is a very palatable beer, whilst containing only a small proportion of alcohol. Messrs. Reinheimer and Co., of Surbiton, Surrey, exhibited examples of nektar wines which represent, in fact, perfectly clear preserved grape juice. The use of preservatives is avoided, pasteurisation sufficing. We have already given analytical details of these excellent preparations. A large variety of aerated waters was shown by Camwal, Limited, of 112, Pembroke-street, Caledonian-road, London, N. These included medicated waters, such as soda, potash, and lithia, piperazine and lysidine, and a natural table water from Harrogate sparkling with carbonic acid gas. Amongst natural mineral purgative waters was the Arabella water exhibited by Arabella, Limited, 2A, Hay-hill, Berkeley-square, London, W., which while containing a satisfactory proportion of magnesium and sodium sulphates is not so nauseous to the taste as might be expected; and Friedrichshall, a less powerful water, but containing a very suitable proportion not only of the sulphates of magnesium and sodium but of the chlorides also (C. Oppel and Co., 10 and 12, Milton-street, London, E.C.) A few English spas were represented, notably Buxton, Harrogate, and Leamington. During the meeting a party was organised to visit the latter spa and to inspect the treatment and arrangements made for patients at that enterprising place. Vichy and Carlsbad waters were well represented at the stall of Messrs. Ingram and Royle, Limited, of 26, Upper Thames-street, London.

VI.—PUBLICATIONS.

Publishers continue to find the annual exhibition a means of introducing new publications to the notice of the profession. Amongst those who had stalls this year were Messrs. W. B. Saunders and Co., of 9, Henrietta-street, London, W.C.; J. B. Lippincott Company, of 5, Henrietta-street; John Wright and Co., of Bristol; Mr. H. K. Lewis, of 136, Gower-street, London, W.C.; Messrs. Cassell and Co., of La Belle Sauvage-yard, London, E.C.; Messrs. Macmillan and Co., Limited, St. Martin's-street, London, W.C.; and Messrs. John Bale, Sons, and Danielsson, Limited, of Great Titchfield-street, Oxford-street, London, W. There also may be mentioned the exhibits of Messrs. W. and A. K. Johnson consisting of a series of 12 diagrams on hygiene intended to illustrate a course of popular health lectures.

VII.—MISCELLANEOUS.

Amongst the miscellaneous exhibits may be mentioned the specialities for weak feet, and natural shape boots, exhibited by Messrs T. Holland and Son, of 40, South Audley-street, London, S.W.; the series of sanitary wood wool preparations by the company of that name, of 26, Thavies Inn, Holborn-circus, London, E.C.; the special wire mattresses for hospital use, for lunatic asylums, &c., by the Longford Wire Company, Limited, Warrington; the aertex cellular clothing of the Cellular Clothing Company, Limited, 72 and 73, Fore-street, London, E.C.; the anatomical boots and invalid boots, by Mr. N. Bletchley, of 89, Northgate-street, Gloucester; the system of keeping medical accounts, by the Trading and Manufacturing Company, Limited, of Temple Bar House, Fleet-street, London, E.C.; the Lawson-Tait spring bedsteads, by Messrs. George Gale and Sons, Limited, of Dominion Works, Birmingham; and lastly an exhibit by Messrs. S. Goff and Co., of 17 and 18, King-street, Covent Garden, in which were included sets of harness, a doctor's gig, and stable sundries for medical men.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. James H. Dunn of Minneapolis, where he was professor of surgery at the College of Medicine and Surgery. His death occurred a St. Louis, where he had gone to attend a meeting of the American Surgical Association.—Dr. Friedrich Heisrath of Königsberg, whose work on trachoma is well known.—Dr. C. A. Gayet, professor of clinical ophthalmology in the University of Lyons.

ANNUAL REPORT OF THE METROPOLITAN ASYLUMS BOARD.

THE annual report of the Metropolitan Asylums Board for the year 1903 was submitted to the managers by their chairman, Mr. Augustus C. Scovell, on July 23rd and has now been issued to the public. The reports of the various committees by which the work of the Board is transacted are contained in a volume of 320 pages, preceded by a list of members of the Board showing the committees upon which they serve and, in the case of those elected by boards of guardians, the unions which they represent. Then follows the report of the Board itself, a brief document signed by the chairman and the secretary, with a list appended of the institutions under the control of the Board or in course of erection by it. A useful index concludes the volume. The various committees which make reports are the general purposes committee, the finance committee, the works committee, the contract committee, the children's committee, the training ship *Exmouth* committee, the asylums committee, the ambulance committee, the hospitals committee, and the statistical committee. To the reports of the committees are added, by way of appendices, reports and statistical tables referring to particular subjects, with maps and charts showing the incidence, fluctuations, and provision for the treatment of infectious disease in London. A medical supplement occupies nearly 50 pages.

During the year 21,925 patients passed through the Board's fever hospitals and 359 through the small-pox hospitals, the principal feature of 1903 being the greatly diminished prevalence of infectious disease as compared with preceding seasons. The number of cases of disease admissible to the Board's hospitals and notified as such were in 1901, 35,311; 1902, 40,046; and 1903, 23,087 (p. 162). For this welcome falling off the abatement of the recent small-pox epidemic was largely responsible, the notifications of this disease having numbered in 1901, 1700; 1902, 7796; and 1903, 416; but a lesser occurrence of other diseases is also conspicuous, the figures for scarlet fever in the three years before named standing at 18,381, 18,252, and 12,531 respectively, the figures for diphtheria in the same years being 11,968, 10,538, and 7582, and for enteric fever 3194, 3407, and 2339. In typhus fever alone there was an increase to 22, the highest number since 1893, but these figures are so small that they do not affect the total, and typhus fever during the years recorded by the Board has fluctuated between 35 cases in 1890, the first year tabulated, and four, which was the total in 1897 and 1902.

With regard to diphtheria an encouraging feature of even more importance than the smaller number of cases is the continued decrease in the rate of mortality since the introduction of the antitoxic serum. The mortality rate among the cases of this disease treated in the Board's hospitals was 40·74 per cent. in 1889, varying between this and 30 per cent. up to the introduction of the serum treatment in 1895. It then fell to 22·85 per cent. The serum is now used at all the hospitals for every case judged sufficiently severe to require it and not too far advanced for it to be useless, with the result that the mortality in all cases of diphtheria during 1903 was 9·69 per cent. It must be remembered that many cases are brought under treatment too late and the figures recorded at one of the hospitals showing the day of the disease on which the antitoxic serum was first used speak even more strongly than those already quoted. At the Brook Hospital between 1897 and 1903 187 cases have been treated with antitoxic serum on the first day of the disease without a single death occurring, and 1186 on the second day with 5·4 and 5 deaths per cent. in the first two years of the series respectively, since which period the rate has been about 4 per cent. In cases treated after the second day the mortality is much higher, ranging up to, and sometimes exceeding, 20 per cent. These figures relating to the success of the antitoxic serum treatment in diphtheria should be studied by the public. The writers in a section of the press who are never tired of attempting to discredit any new treatment which they can class with vaccination as "introducing poison into the human frame," and who are abusive of all discovery if they suspect that experiments upon animals have assisted in its development, have misled the public about the value of antitoxic serum. The public should remember that the figures now cited are incorporated in the report of a body of unprejudiced business men elected for the purpose of seeing that the public treatment of infectious disease in the metropolis is efficiently carried out.

In the report dealing with the small-pox hospitals in 1903 an experiment is recorded (p 234) which was made in accordance with the claim of Dr Finsen that the exclusion of all but red light from the wards in which small-pox patients were being treated had the effect of preventing the suppuration of the vesicles and pitting, of abolishing the suppurative fever, and of lowering the mortality No such effects were observed in a small ward of the Long Reach Hospital, from which all but red light was excluded by means similar to those used in constructing a developing-room for photographic purposes. In addition to the absence of any curative effect the gloom was believed to have a deleterious effect upon the general condition of the patients [1]

The medical supplement to the report consists mainly of tables. Three of these relate to the incidence of complications of scarlet fever, diphtheria, and enteric fever, and one gives details of 378 instances (2 19 per cent. of the whole number of infectious cases) in which two or more infectious diseases were co-existent at the time of the patient's admission to the hospitals. With the tables relating to diphtheria are particulars of the fatal cases in which antitoxin was not administered (p. 292) Of these (11 in all) five were moribund on admission and six were cases in which no benefit could have been derived from antitoxin. Two notes conclude the medical report contributed by Dr. H W L Barlow, assistant medical officer at the Park Hospital, upon Purin Compounds in Nephritis and on Vincent's Tonsillitis.

Reference should be made to the report of the ambulance committee (p 148) as one of general interest to medical men in London and to their patients, particularly to those of small means. The committee declares itself aware of the great need felt in London for an efficient public ambulance service for the conveyance of patients suffering from non-infectious diseases as well as for infectious, but not notifiable, cases It states that it had communicated with the local authorities and with the hospitals and had found a considerable majority of opinion in favour of steps being taken for the provision of such a service. It therefore advised the general purposes committee in favour of the proposal that the Metropolitan Asylums Board should be the public body responsible in the matter, and since then the managers of the Board have applied to the Local Government Board *for the authority necessary for them in order to* promote the undertaking No reply on the subject has yet been received The cost of the proposed service would be covered, the ambulance committee states, by a charge of 7*s* 6*d* for each single journey by a one-horse ambulance within the metropolitan area

In the report of the finance committee (p 6) a paragraph of some importance to medical men about to take service under the Metropolitan Asylums Board appears and is as follows —

> Several recommendations from the central committee for the addition of a number of years to the actual period of service of officers under their control have been remitted to and have been carefully considered by us but in no case were we able to find any special circumstances or peculiar professional qualifications which would have justified us in recommending the managers to grant any addition.

The amount which such additions to pensions as those referred to would add to the expenditure of a Board, the yearly outgoings of which exceed £1 100,000, would be insignificant compared with the effect in securing willing and efficient service. But judicious liberality to their medical officers does not seem to form a part of the policy of the Board Take, for example, the case of Dr W. Gayton, whose retirement after 34 years service under the Board is just announced In the small-pox epidemic of 1870 Dr. Gayton treated 12,000 patients without medical assistance In the small-pox epidemic of 1891 he prepared and opened the camp hospital at Darenth at a few days' notice and subsequently opened the hospital ships in addition to his work at the Eastern Hospital. He conducted the North-Western Hospital so that it proved in working the most economical of all. He has frequently been thanked and commended for his services in the course of a long and arduous career spent in the service of the Board. Moreover, there is a feature in his superannuation which merits observation. The *Poor-law Superannuation Act*, 1896, *provides* that "when an officer or servant has attained the age of 65 years and the guardians or managers are of opinion that it would be expedient in the interests of the public service that he should cease to hold his office or employment, it shall be competent for them to require him to retire upon payment to him of his superannuation allowance to which he may be entitled by the Act" The Board does not appear to have retired Dr Gayton under this section. It has made an order of its own under which he has fallen automatically. It runs as follows. "In the opinion of the managers it is expedient in the interests of the public service that every officer or servant in the employ of the managers shall cease to hold his office or employment so soon as he has attained the age of 65 years, unless the managers shall pass a special resolution to the effect that his retirement will cause inconvenience to the public service, in which case he shall [illegible] so on at the termination of [illegible]" This is very different from [illegible] ch case by the Board before the officer retires, and a substantive finding that the individual officer is unfit, a preliminary which the Act enjoins It would be interesting if it could be tested in a court of law whether officers retired under the order of the Board have been legally removed or not, or whether *the resolution being ultra vires they are entitled to their full* pay until proper steps have been taken by the Board in order to deprive them of it In any case the question of possible future generous treatment or the reverse should be carefully considered by medical men before engaging to serve the Board If ever an officer merited special consideration from a public department that officer was Dr Gayton But his deserts have not saved him.

New Inventions.

A NEW REGULATING INHALER.

A FORM of inhaler, a portable apparatus intended for home use *by patients in the treatment of diseases of the lungs* and air passages, has been devised by Dr Anton Bulling of Reichenhall under the name of the Regulating Inhaler or Thermo-Variator It is made principally of highly *glazed white porcelain and when standing on a table* put together ready for use measures about 22 inches long and 11 inches high The part shown on the right hand of the illustration contains a sheet metal boiler heated by a spirit lamp The fluid to be inhaled is placed in a shallow open pan from which it is drawn up by the current of steam and converted into very fine spray at the nozzle, the jet of spray being directed horizontally through the wide porcelain tube towards the mouth of the patient. At its large end this tube has a number of broad apertures for the admission of air, capable of exact regulation by a sliding external metallic tube The temperature of the mixture of spray and air is shown on a thermometer which projects externally Two outlets for the spray are supplied, one a mouthpiece having a single orifice and the other a double orifice for inhalation by the nose. The material and construction of the inhaler enable it easily to be cleaned and rendered aseptic It may, if required, be used for medicating, disinfecting, or moistening the atmosphere of a room as well as for direct inhalation. The representatives of the German manufacturers for the *United Kingdom* are Messrs. F Krasa and Co. of Wood-street-square London, E.C

THE LANCET.

LONDON: SATURDAY, AUGUST 13, 1904.

Municipalities and their Duties.

WE have lately had to call attention to the good fortune of the borough of Wigan, as displayed by its possession of an organised body of citizens sufficiently energetic and sufficiently enlightened to take a proper interest in the doings of the local authorities, to stimulate them when torpid, to restrain them when mischievously active, and generally to bring their deeds and defaults prominently to the notice of the ratepayers by whom they are from time to time elected. We are not yet able to extend the same congratulations to the ratepayers of Liverpool; but we have read with great interest and pleasure a publication which seems to render it probable that a similar organisation will before long be formed there. The publication in question is entitled "Municipal Shortcomings," and it is a reprint of a series of 25 articles contributed to the *Liverpool Journal of Commerce* by Mr. T. MYDDELTON SHALLCROSS. The author took as his original text the fact that the death-rate of Liverpool is unduly high; and he argued generally that, as a high death-rate is usually or always traceable to obvious insanitary conditions, and as the municipal authorities are the persons by whom insanitary conditions should be rectified, the high death-rate must, *a priori*, be directly traceable to their sins of omission or commission. He further proceeded to trace the causes of these sins to the circumstance that the persons guilty of them are not in the first instance selected with any reference to their fitness for the work which it becomes their duty to accomplish, but solely from what are called "political" considerations, as well as to the additional circumstance that the chairmen of committees and other officers do not retain their positions for a sufficient time to render them conversant with the details which it should be their endeavour to master or with the laws which it is their business to carry into effect. From the standpoint thus indicated he pushes his inquiries into nearly every one of the chief branches of urban local government and describes in telling language the very little that is done and the great deal that is left undone. The chief heads of the resulting indictment may be summed up under neglect of scientific knowledge, neglect of the sources of diffusion of infectious diseases, neglect of cleanliness, inefficient control of adulteration and of food and milk supply, neglect of the supervision of kitchens, and neglect of the supervision of manufactures, especially of the manufacture of clothing. He further dwells upon the general ignorance of cooking and upon the neglect of cooking by the community, but these are surely matters for which the local authorities are at present scarcely more responsible than the citizens generally. Now that the powers of the former extend to the control of education they may reasonably be expected to regard good cooking as a consequence of instruction rather than as a gift of nature.

Mr. SHALLCROSS enters into detail with regard to nearly all the counts of his long and varied indictment, but inasmuch as details of this kind will seldom be the same in different places it is not necessary to occupy space in describing them. His general principle is, we think, indisputable, although there are probably many persons, and among them many borough councillors and such like people, who will regard this principle much as LOUIS XIV. regarded the opinion of his grandson that subjects were not created solely for the benefit of kings. Mr. SHALLCROSS holds that it is the duty of local authorities to exert to the full the whole of the powers conferred upon them by law for the protection of the community against disease and other preventable evils and that it is equally their duty, when experience has proved these powers to be in any particular inadequate, to seek for their increase in the proper directions and to the necessary extent. As a corollary to this opinion he holds also, it need hardly be said, that it is the duty of ratepayers to give their votes to men who will accept and endeavour faithfully to discharge the responsibilities of their position, and who will not be content with "representing" the Submerged Ward in the interests of so-called Liberalism or Unionism, but will set to work at cleaning its thoroughfares, at abolishing its nuisances, and at purifying its slums. The complete justice of his criticism may be illustrated by an arrangement of which we were cognisant, and which was made in an important manufacturing town in the Midlands in the course of the last century. Party politics ran high in the place and the "Liberals" had a small but decided majority. It was so small that seats in the town council were frequently disputed and much expense was incurred in contested ward elections. The Liberals offered a compromise. If the Conservatives would not seek to enter the town council they should be permitted to reign undisturbed in the board of guardians. The offer was accepted with an understanding that the proceedings of the latter body should be fully reported in the local papers. The town councillors were thenceforward all Liberals, and their official duties were practically limited to the management of little jobs for the benefit of members of their "party." The guardians were all Conservatives, and at every meeting of the board they delivered their opinions about things in general, and the conduct of the Government in particular, to a bevy of pressmen, by whom their words of wisdom were duly communicated to the rest of the inhabitants. The speeches having been made, the speakers went away in a body and left the unimportant business of the relief of the poor to be settled by the clerk and the vice-chairman.

All diligent students of the "Pickwick Papers" have been made aware that "the word politics comprises in itself a difficult study of no inconsiderable magnitude," but this view of the case has failed to commend itself to many municipal councillors who have often fallen into the error of regarding themselves as being primarily concerned with the affairs of the kingdom and only secondarily with those of the borough. Their error has been confirmed by the fact that the leaders of political parties have persistently regarded "parochial" as a term of contempt, and have as persistently thwarted the efforts of those who have aimed at sanitary improvement, lest its attainment should give umbrage to many of their followers The great health officer who has recently closed his career was occupied during the last years of his official life in vainly pressing the need for reform upon the attention of the Government and of Parliament, and there is, perhaps, some reason to hope that the good seed sown by him is now beginning to bear fruit The cowardice of professional politicians is generally at least as conspicuous as their ignorance of all scientific questions, and it is probably hopeless to expect any effective aid from ministerial quarters But the most exalted personage in the realm has struck a keynote by his pertinent inquiry why, if tuberculosis be preventable, it is not prevented? and some answer to this question will be insisted upon by the public Mr **SHALLCROSS** has, we believe, taken an important step towards supplying it He has shown that the municipality of one of the chief provincial cities quietly accepts an abnormal death rate many of the causes of which are well known and even conspicuous, and he considers that nothing more than half measures have been employed for dealing with them Mr **SHALLCROSS** places the responsibility for these unnecessary deaths upon the municipality, and it is difficult to see in what respect his argument is defective or why it should not be applied in other places and to other authorities

◆

The Nature and Etiology of Cancer.

CANCER theories have been propounded for generations almost as a matter of course As a result there has accumulated a plethora of speculation based upon certain facts, the number of which has shown an annoying tendency not to increase Those men who in their day have been most in touch with the trend of scientific thought and progress have formulated theories which have been sober efforts to mould anew the same old facts into a form in keeping with the sum of human knowledge at the time We may almost say that each decade of the past half century has had its cancer theory *par excellence* Each decade has also had its share of fantastic speculations—wild shots in the dark—only justified apparently by the fact that their authors were the first to give them publication The quack who proclaims that he has a sovereign remedy ' for the largest spider cancers, drawing them out with all their tentacles ' or " causing them to drop out like bulbs with roots on them ' by means of a " draft with more business in it than a dozen plasters is not wider of the mark in treatment than many who even to-day attempt to explain the mystery of cancer by adding one more to the already too numerous hypotheses The theories of the past and of to day fall into the same two categories the explanation is sought either in causes intrinsic to the body or in the influence of extraneous agencies on the body The problems of cancer are nowadays believed by many to require more resources than individual effort can supply The recognition which has thus far been accorded to the combined efforts of the Imperial Cancer Research Fund and other similar organisations in this country and abroad indicates that the individual investigator who has not also the backing of some extended organisation will in future work under greater disadvantages than in the past

In the regulations of 1793 relating to infectious diseases in Germany "cancer was included At the present time there is a strong movement in that country, headed by **VON LEYDEN**, to make cancer a notifiable disease The evidence on which ' cancer" was included among the infectious diseases of 1793 may have been more convincing at that time than any which the advocates of the infectious nature of cancer are able to adduce to-day The parasitic theory of cancer is the modern expression of a belief in an extrinsic causation Macroscopic, microscopic, and ultramicroscopic parasites have been asserted to stimulate cells to cancerous growth The alleged parasites have been cultivated and they have been seen to proliferate on the warm stage of a microscope The limited epithelial proliferation in some of the most infectious of diseases—e g , vaccinia—has been compared to the unlimited growth in cancer, and to give point to the argument the two have been designated "epithelioses' and 'epitheliomas respectively The belief in the parasitic nature of cancer may be defended by the assertion that the parasite differs from any form known, so that although cancer is an infectious disease it is so in an entirely new sense The belief in a parasitic etiology is obviously a manifestation of a reaction in what may be styled the bacteriological epoch against the cellular teaching The **COHNHEIM** theory postulated the occurrence of "embryonic rests the sites where they occurred and their possession of powers of growth Time has shown that embryonic rests do frequently occur but it has also as surely shown that displaced embryonic or adult cells are not endowed with unlimited powers of proliferation The negative results of all previous conceptions of an intrinsic etiology naturally led to a reaction in favour of the extrinsic theory and to the development of the parasitic or infectious hypotheses on rational and even irrational lines Its advocates have repeated the errors made by those whose views they have sought to replace They have postulated infectivity and the possession of powers of growth by infected cells, but the facts have refused to keep pace with such hypotheses and have shown in the few cases in which cancer has been experimentally transmitted to a new host that there is nothing of a true infection but only a continued growth of the original cancer cells themselves

It is a sure sign of the waning power of one cancer theory when following a new lead fancy begins to run wild along other lines Recent research has added some new facts to our knowledge of cancer, has placed the problem upon a more comparative basis than has hitherto been attained, and has adduced proofs in support of the view that the problems of cancer as they present themselves throughout the vertebrate kingdom are essentially cell problems All that the original observers have done has been to record their observations and to formulate what they believe may be useful, if contradictory, working hypotheses Before even these observers are at one as regards the interpretation to be put upon some new features in the division of cancer cells, or the facts themselves have received general recognition, the speculator is again to the fore with dogmatic statements backed by no proofs. At the present time our knowledge is so limited that it is wise to avoid entirely all dogmatic utterances, and in this connexion we refer our readers to the account of two demonstrations at the Oxford meeting of the British Medical Association which is published in this issue of THE LANCET. One of these demonstrations claimed to show that in a malignant growth the cells have taken on a likeness to reproductive cells, and the other demonstrated the parasitic nature of malignant disease. In each case the work is a model of what scientific work should be, the investigators have taken all possible pains to eliminate error, to be clear, and not to make extravagant claims. To the value of the work done by Professor J. B. FARMER, Mr. J. E. S. MOORE, and Mr. C. E. WALKER, we have already borne testimony in our columns. The researches of Dr. W. F. ROBERTSON and Mr. H. WADE show that the school which regards bacterial infection as the origin of cancer is also active. Let those who in future essay to advance our knowledge of cancer regard it as their first duty to add *new facts* to those long known. They may be more difficult to find than new explanations of the old ones but their accumulation will assuredly point somewhere much more definitely than the too many explanations of the old facts have done.

◆

The General Management of Chronic Diseases of the Heart.

IN a paper which appeared in our columns last week by Dr. J. HILL ABRAM attention was drawn to certain points in the diagnosis and treatment of heart lesions, the practical lesson of the writer being that the therapeutics of chronic diseases of the heart present many problems which demand greater attention than is usually devoted to them. The treatment of well-marked cardiac failure is understood by practitioners and appreciated by patients, but when the malady has assumed a more chronic condition the perseverance of the medical man and the patience of the sufferer are both severely taxed. During what may be termed the acute stage of cardiac disease all efforts are devoted to the establishment of satisfactory compensation—the mechanism of the circulation has to be adjusted—but subsequently the maintenance of that compensation is equally important and demands a vast amount of care and attention. The hearty coöperation of the patient with the efforts of the practitioner is necessary for a successful result, but unfortunately it is an open question how much the former should be taken into the confidence of the latter. As a rule of life, as well as of sensational fiction, confederates only succeed when they are completely candid with each other. But we doubt whether it is beneficial, as Dr. ABRAM would have us think, that the exact state of affairs should be explained to the sufferer from chronic heart disease. The use of the term "heart disease" to a patient is frequently productive of great depression, which it is important to avoid, whilst the necessary injunctions can generally be given with sufficient emphasis without either minimising the seriousness of the condition or pronouncing words that to the lay mind sound like a death warrant. There is among laymen a general impression that "heart disease" is incurable and to some extent, of course, this is right. But the physician is aware that if certain maxims are observed in many cases life may be prolonged for some years, for a sufficient number of years, perhaps, to enable the patient to die of old age. And the mode of living that should be enjoined upon the sufferers from chronic heart disease does not necessarily entail very irksome restrictions.

There are certain principles which have particularly to be borne in mind in directing the management of a case of chronic cardiac disease. Three of these are of the utmost importance—namely, (1) to sustain the force of the heart; (2) to insure that its nutrition is maintained; and (3) to reduce the peripheral resistance. It is to the first of these that the main efforts are usually directed but the other two are of equal, perhaps of even more, importance. Drugs alone cannot be relied upon, although their influence in certain cases and directions may be very marked. Success in treatment greatly depends upon the manner in which the patient controls his whole mode of life. The force of the heart, it is true, can be most readily sustained by such drugs as digitalis and strychnine but its nutrition can more easily be maintained by means of massage and the mechanical methods introduced by ZANDER of Stockholm in 1872, the graduated walking exercises of OERTEL, and the resistance exercises of the brothers SCHOTT. The object of all these measures is to stimulate the arterial circulation in the muscle, to hasten the venous currents, and to promote the passage of lymph through the lymphatic channels; the metabolism of the body is thus maintained, and digestion is improved in those individuals who from any cause are unable to take active exercise. Massage in particular is able indirectly to influence the coronary circulation in those who are bed- or sofa-ridden and thus the desired improvement in the nutrition of the cardiac muscle is brought about. Graduated exercise has been found to be a valuable therapeutic measure if carried out under skilled advice. It probably acts in two ways—partly, as we have pointed out, in improving nutrition and partly by reducing the peripheral resistance. We need scarcely remind our readers of the well-known physiological fact that a muscle in action requires more blood than when at rest; consequently sustained moderate use draws a quantity of blood from the general circulation into the muscles and so relieves the distended chambers of the heart. In our opinion, sufficient stress is not generally laid on the relief that may be given to the heart by bringing about dilatation of the arterioles. This may be accomplished not only by exercises of the nature above suggested but also by the administration of such drugs as the alkaline iodides and carbonates, or by nitro-glycerine or nitrite of amyl. Great assistance can be rendered by careful regulation of the patient's diet, the state of the bowels, and the daily amount of ordinary exercise, for by such general disciplinary attention the special therapeutics, whatever their nature, are much reinforced.

There are certain symptoms caused by defective cardiac power which add greatly to the patient's distress but which often do not receive adequate attention. Dyspnœa, palpitation, and "dropsy" are phenomena which the laity constantly associate with "heart disease," but apprehensiveness, restlessness, sleeplessness, and digestive troubles are less obviously to be attributed to a cardiac cause. Nevertheless they often exist and if they can be overcome great general improvement will be found to follow. An easy and regular circulation through the brain is accompanied by a sense of security and comfort; when the cerebral circulation is insufficient certain nervous manifestations are likely to ensue. The means which we have already indicated will naturally be the chief elements in lessening those symptoms but much can be done by a judicious and tactful practitioner in reassuring the patient and calming his fears. To procure sleep in cardiac cases may sometimes be a matter of great difficulty. Amongst the less powerful hypnotics which are employed in cardiac cases we are inclined to give the first place to chloralamide. The amount may gradually be increased to considerably beyond the ordinary pharmacopœial dose and its use may be prolonged without harm. The dyspepsia of cardiac disease is also difficult of treatment. The old French maxim that a patient with heart disease complains of his stomach and a patient with gastric disturbance of his heart may be generally accepted. If the circulation of the stomach is disturbed digestion is, of course, interfered with and the correct treatment will be to improve as far as possible the cardiac power. But this does not mean that the therapeutic measures are to be solely cardiac in intention; on the contrary, the symptoms of dyspepsia may often be combated with appropriate remedies. In short, we must never forget, and must never allow our patients to forget, that by general treatment much may be done for patients suffering from chronic disorders of the heart.

Annotations.

"Ne quid nimis."

THE PRESIDENTIAL ADDRESS AT THE PHARMACEUTICAL CONFERENCE: THE MEDICAL MAN AND THE DISPENSING OF MEDICINE.

THE address to the members of the British Pharmaceutical Conference, which meets this year at Sheffield, was delivered by the President, Mr. T. H. W. Idris, the mayor of the borough of St. Pancras, on August 9th and will be published in the *Pharmaceutical Journal*. We recommend our readers to read it there, as it will be found both of interest and instruction. Most of the address was, as was to be expected, of more concern to pharmacists than to medical men, but Mr. Idris's remarks upon the chemistry of the essential oils have a wider bearing than appears at first sight. He showed how the superiority of natural essential oils over the synthetic preparations was due to the fact that the natural oils are chemically impure. So in the same way the superiority of pot-still brandies or whiskies over the fluids which manufacturers euphemistically call "blends" is due to the fact that the genuine pot still spirit is chemically impure. Mr. Idris passed on to consider the position of poison legislation and pharmacy legislation and referred to the Pharmacy Bill which failed to obtain a position this year in the House of Commons. It is much to be hoped, however, that next year will see some legislation carried whereby absolutely unqualified persons may be prevented from trading as pharmaceutical chemists or from dealing in poisons intended for internal use. Mr. Idris next referred to our singularly lax system of death certification and concluded his address by dealing with the difficult question of dispensing by medical men. This is the portion of the address which has most interest for members of the medical profession and we give Mr. Idris every credit for the temperate way in which he stated his views. In his address to the Pharmaceutical Conference which met last year at Bristol Mr. Idris spoke on this matter at length and he returns to the subject with zeal.

> "It is an anomaly," he says, "that chemists dispensing should be governed by certain regulations but that a doctor should be free to carry on the important function of dispensing in whatever fashion he [illegible] chemist."

The question of medical men dispensing their own drugs must always be a difficulty, and many would welcome a change whereby the public came to recognise that medical fees were due for expert advice and not for something in a bottle. But in many districts there is not a large enough population to support a duly qualified pharmaceutical chemist as well as a medical man and it would be impossible, as far as we can see, to devise legislation which should prohibit a medical man from dispensing in a district where a pharmaceutical chemist was available while allowing him to do so in the contrary case. Mr. Idris points out that pharmaceutical chemists have no wish to usurp the functions of the medical man and this is no doubt true of the best of them, but we have heard of counter prescribing. The preventing of pharmaceutical chemists from prescribing seems to us as difficult by law as the preventing of medical men from dispensing. So long as any person is allowed to practise medicine provided that he does not imply that he is a registered medical man it must be unfair to impose particular disabilities upon a class which, though uneducated in medicine, yet knows something of practical therapeutics. And so long as the community cannot pay both the medical man and the dispensing chemist the medical man will have to discharge the double duty.

THE ADULTERATION OF FOOD AND DRUGS.

IN an annotation which appeared in THE LANCET of June 25th, p. 1807, under the title "Bread and Butter," attention was called to the observations of Dr. William Collingridge upon the substitution of other fats for butter, particularly in the case of "bread and butter" sold as such in small eating and coffee houses in London. The report of Mr. Edward Sergeant, medical officer of health of Lancashire, contains an analysis of the prosecutions which took place in that county under the Sale of Food and Drugs Acts during the quarter ending June 30th, and in the particulars given the adulteration of milk and butter and the passing off of other substances for the latter are conspicuous. Within the period named legal proceedings were taken in 52 cases and in 42 of these the magistrates, having found that the article sold was not of the nature, substance, and quality of that demanded, inflicted fines which cannot be regarded as outrageously severe, for they amounted only to £82 19*s*. in all. In many cases only the payment of costs was ordered. Of the ten charges upon which there was no conviction two were withdrawn after the conviction of the defendant in another case had been secured, and four were dismissed upon the defendant producing a warranty from the dealer who had supplied him. Of the remaining four, three were dismissed by the bench and one was withdrawn. Of the 42 convictions obtained six related to butter, all but one being in respect of excess of water, and the sixth being grounded upon the presence of 0·94 per cent. of boric acid. Eight were for margarine sold without proper intimation of its character. 16 convictions were obtained in milk cases, two on account of the presence of formaldehyde in the proportion of approximately 1 to 100,000 parts, two on account of subtracted cream, and the remaining 12 for added water. Thus substitution and adulteration in the case of dairy produce were responsible for 30 out of 42 convictions in which the purity of the food of the people was involved. Of the remaining 12 no less than seven successful prosecutions were in respect of pepper, which was mixed chiefly with its own husks bleached or partly bleached and dyed; in one instance, however, ground olive stones formed the adulterant. There were two cases of selling whisky and one of selling rum under proof and there was an important conviction for the sale of brandy containing upwards of 70 per cent. of neutral spirit not derived from grapes. With reference to this it may be noticed that two charges were dismissed of selling as brandy spirit not to any extent derived from grapes. This was done upon warranties being produced from the original vendors and these were impounded by the court. The remaining conviction making up the total was for selling as golden syrup a mixture containing 50 per cent. of starch sugar syrup. The greatest amount of adulteration and deception therefore, according to these figures, takes place in those articles of food the purity of which is of most importance owing to their being articles of universal consumption and owing to their forming an important portion of the diet of children.

THE CASE OF DR. F. J. HICKS.

As we have announced already Dr. Frederick John Hicks was acquitted last week at the Central Criminal Court where he was indicted on a charge of having procured criminal abortion upon a young married woman. There were circumstances about the case, all of which are obvious to our readers, that made the issue appear doubtful. Neither Dr. Hicks nor those who assisted him in his defence could possibly have been blind to the force of some of the arguments of the Crown, so that the protracted period of delay during which he was under remand must have been a time of terrible anxiety for him. We congratulate him upon the decision of the jury, whose verdict discharges him from the case without a stain upon his character, and who, in rendering their verdict, certainly acted in complete accordance with the evidence. Leaving aside many weighty considerations that made Dr. Hicks's guilt improbable, and looking at the charge only as it was formulated, it must not be forgotten that the alleged criminal act was one of extraordinary imbecility. Dr. Hicks was accused of having attempted to procure abortion upon a young married woman by inserting a self-retaining stem-pessary into her uterus, sending her home with the instrument still within her, in case, as it were, any doubt should arise as to the nature of his illegal operation. Surely if his action had been criminal in intent his folly was incredible. Secondly, the incriminating correspondence which, as we consider rightly, was not held by the jury to be incriminating at all, was lying loose in his consulting-room. It is an old experience of the police in criminal cases that the most damning letters are occasionally retained by accused persons, but that a physician having the crime of criminal abortion upon his conscience should leave the documents in proof of the same open upon his desk for months together passes the bounds of belief. The use of the intra-uterine stem-pessary, though so fatuous a method of procuring abortion, was formerly the recognised treatment for the reposition of a displaced uterus. This was the teaching in the medical schools when the expert medical witnesses in the case, Dr. Champneys, Dr. Lewers, Dr. Horrocks, Dr. Luff, and Mr. Pepper, for example, were students. Gynæcology has developed during the last 20 years and Dr. Hicks's method of treatment would not now be considered up to date in most cases. But if his procedure was obsolete when directed against anteversion, as a method of procuring abortion it would have been so astoundingly incriminating for the operator that the jury rightly agreed to acquit him of criminal intent.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

At the Mansion House on August 9th the Lord Mayor of London presided at a meeting of the Council of this Fund, which was held for the purpose of receiving the report of the committee of distribution. The committee recommended awards this year to 215 institutions. The amount of collections, including interest from the Court of Chancery, to the present time is £59,360. The distribution of £56,371 *8s. 4d.* to 157 hospitals and 58 dispensaries is now recommended. This year 218 institutions have made application for grants from the Fund, being seven more than in 1903 and just double the number that applied in 1874. The adoption of the report, which was carried unanimously, was proposed by the Lord Mayor and seconded by Sir Sidney Waterlow, who for the past 32 years has acted as chairman of the distribution committee. Among the speakers who referred to matters of pressing importance with regard to hospital administration were Sir Henry Burdett, who pointed out that those institutions which were controlled by a medical superintendent showed less expenditure per bed, and Dr. J. G. Glover, who called attention to the increasing and curiously varying cost of out-patients in different hospitals. The amounts per patient varied from 1*s.* 6*d.* to 7*s.* 4*d.* per head. When presenting, as usual, the list of awards we may take the opportunity to refer at greater length to some of the important matters touched upon at the meeting.

THE PASSING OF THE CHIMNEY.

Industrial pursuits inflict upon us many kinds of offence and commendable as is the activity of our public health authorities they have, of course, no power to remove offences which affect the eye. Such a power would open the door, we suppose, to vexatious proceedings, and yet who shall decide which is the greatest offence, that which affects the sense of smell, of sight, or of hearing? There can be little doubt that noise can be a source of ill-health just as much as evil smells, but it would be more difficult perhaps to establish that a blot upon the landscape is in the same degree harmful. All the same few will deny that a prospect can be, so to speak, noisome to the eye and when the harmony of a prospect is ruthlessly disturbed the eye that detects it transmits a feeling of pain to the whole system. "It gets on one's nerves," we say of an ugly sight as of an ugly sound, and the expression has a substratum of physiological truth. Progress day by day teaches us how barbarous are some of our industrial methods. What can be more hideous to the sight than a forest of factory chimneys and, after all, the chimney is man's simple but clumsy design for the creation of a draught, and the landscape must be marred because the manufacturer wants an abundant supply of oxygen to feed his furnace fires. There is some hope, however, that the factory chimney may soon give way in favour of a system of forced draught. Already destructors, which have hitherto sadly disfigured many a picturesque spot on account of their ugly chimney shaft, are being constructed without a chimney. A simple method of forced draught replaces the function of the offensive shaft, and not only is it more effectual for purposes of combustion, but it reduces the immense cost entailed in constructing a chimney stack 100 feet or so high. We may be sure that the economy of the principle will appeal to a manufacturer even if a sense of beauty does not. The day may come when domestic chimneys may be done away with by the adoption of the forced draught and at length the realisation of smokeless London is suggested as a pleasing outcome.

MEDICAL EDUCATION IN ST. PETERSBURG.

THE new statutes of the St. Petersburg Women's Medical Institute have just been published and open a new era in the history of the education of Russian women who in respect to medical education and practice are practically on the same terms now as doctors of the male sex. They may obtain diplomas, pursuing their studies for medical degrees in the universities of the country and in the Military Medical Academy. "Henceforth," says the *Novosti*, "the Russian woman, having brilliantly distinguished herself in various scholarly careers, is free to participate in the general work of the laborious field of medicine." The Russian female medical students have for a long time been distinguished for their energy and enterprise in several of the best known continental schools and they will for the future have proper opportunity for exercising their talents in their own country. The new law limits the age of those who may be received into the institute to women not younger than 19 years and not over 28 years. It also limits the number of students of the Hebrew faith to 3 per cent. It is by such funny exhibitions of barbarism that Russia is always revealing herself to the rest of Europe as hopelessly behind the times. The female medical practitioner is not, of course, unknown in Russia. The first Russian lady doctor to practise was Madame Sussolovou who, having obtained diplomas abroad, for a long period had a successful practice in St. Petersburg.

OCULAR PARALYSIS IN GRAVES'S DISEASE.

IN addition to the usual ocular signs of Graves's disease paralysis of one or more of the extrinsic ocular muscles occasionally occurs. In the *American Journal of the Medical Sciences* for July Dr. W. C. Posey has recorded the following case. A woman, aged 43 years, was admitted into hospital on account of failure of sight. She had had poor health for about ten years and suffered from palpitation of the heart and nervousness. For several years she had suffered from pains in the supra-orbital and temporal regions. Her sight had been good until two months before she went to the hospital, when she began to see double. She was not aware of any swelling in the neck. There was slight proptosis, especially of the left eye, and the palpebral fissures were widened. She fixed with the right eye, the left being rotated downwards and outwards. Von Graefe's sign was found in both eyes at times; at others it could not be demonstrated. The left eye could not be rotated upwards above the horizontal line; external and internal rotation were limited; downward rotation was good. A study of the double images showed that there was paralysis of the sixth nerve and of that portion of the third which supplies the inferior oblique and superior and inferior recti muscles. The thyroid was slightly prominent and the pulse was 110. Prolonged rest in bed was recommended but after a few weeks the woman became impatient and left the hospital unimproved. Ocular paralysis in Graves's disease may be limited to a single extrinsic muscle or may affect all the extrinsic muscles of one eye; occasionally both eyes are affected. Paralysis of the ciliary muscle has not been recorded, nor of the associated movements of the eyes except convergence. Paralysis of the levator palpebræ superioris may occur and sometimes is accompanied by paralysis of the other branches of the third nerve. Paralyses of other cranial nerves have been reported. Bristowe has described a case in which ophthalmoplegia externa came on three years after the onset of Graves's disease. There were also slight hemianæsthesia, colour blindness, and loss of smell and taste on the same side. The patient died from bronchitis and the necropsy showed no changes to account for the paralysis. In a case reported by Warner there was double ophthalmoplegia externa with paralysis of the fifth and facial nerves. Jendrassik has described paresis of the muscles of mastication in conjunction with paralysis of the ocular and most of the facial and palatal muscles. The pathology of paralyses in Graves's disease is not definitely known. The cases of more or less complete ophthalmoplegia externa, and especially those in which there were associated lesions of the facial, hypoglossal, and glosso-pharyngeal nerves, seem to show that the paralysis is of central origin and due to nuclear changes. The paralyses seem to be only functional, for they are sometimes transient and the necropsies which have been made were negative.

A SAFETY HELMET FOR FIREMEN AND OTHERS.

WE have received from Dr. Guglielminetti of Paris a description of an apparatus devised by him for firemen, rescue parties in mines, and others for whom it may be necessary to move about with safety in an irrespirable atmosphere. The details of the apparatus are strongly reminiscent of the cylindro-conical projectile devised by Jules Verne for the journey to the moon and in which J. T. Maston lived for a week and grew fat. It consists of a helmet something like that of a diving dress but made of aluminium instead of copper. This helmet is entirely cut off from the outside air by means of a pneumatic collar. Underneath the chin piece of the helmet is a sack, called the respiratory sack, which, to commence with, is full of air. The oxygen of this air is constantly renewed from a small cylinder of that gas which is carried at the back of the person using it. The expired air passes through some cooling coils and is purified of its carbon dioxide by means of caustic potash, while the nitrogen is simply used over again. Enough oxygen can easily be carried to enable a man to stay for at least 30 minutes in an irrespirable atmosphere and, in fact, on July 2nd a fireman remained for 38 minutes in a closed cellar filled with the smoke from damp burning straw and came out none the worse. From the accounts of experiments made with the apparatus it would seem to be of great value for rescue parties in mines and for firemen, though in the case of the latter, as the oxygen is compressed in the cylinder, the question of possible explosion from heat might have to be considered. The Paris fire brigade, however, appear to be well satisfied with the apparatus.

PUBLIC ELEMENTARY SCHOOLS AND MEDICAL INSPECTION.

ON August 2nd the council of the Richmond (Surrey) corporation, acting upon the advice of the education committee, sanctioned the appointment of the medical officer of health as medical officer to the education committee at a remuneration of 50 guineas per annum for the purpose of medical inspection of scholars attending the public elementary schools and for other duties under that committee. We are glad to see that the local authority has recognised that it is its duty to obtain medical inspectors for scholars attending the elementary schools, and it is without doubt an advantage that such inspection should be performed through the health department. It is also gratifying to see that the education authority has grasped the principle that such duties are additional to the ordinary work of the medical officer of health, as is shown by the grant of extra remuneration. In addition to this departure the education committee has granted a sum of 25 guineas to the medical officer of health and the borough surveyor respectively for a joint report upon the structural and sanitary condition of the public elementary schools. The report deals with nine schools and the reporters say that in general the schools have been well kept up. In most of them, however, various structural alterations and additions appear to be necessary. Altogether we congratulate the Richmond corporation upon its sensible attitude. There is scarcely any agent so capable of spreading infectious disease as a public elementary school and to no institution does the proverb, "Prevention is better than cure," so forcibly apply. Careful inspection will not only bring about saving of life and prevention of disease but will also spare the pockets of the ratepayers.

A SUNDAY LEAGUE EXCURSION AND RAILWAY MISMANAGEMENT.

HOW badly some of our railway companies—and the South-Eastern Railway in particular—muddle through their attempts to deal with a holiday crowd was in evidence last Sunday at mid-day at Charing Cross Station when one of the platforms was packed with men, women, children, and babies going on a Sunday League excursion to Margate, Ramsgate, Hastings, and elsewhere. There was no train at the platform so that people could take their seats as they arrived. The officials waited until the platform was so crowded that no one could move and then they backed the train into the station, with the inevitable result—a mad and dangerous struggle for seats, rendered all the more severe by the knowledge that all cannot possibly be wedged into the train, in which women and the poor little children and babies suffer considerably. It is no exaggeration to say that the scene last Sunday on the Margate train being backed into the station was a positive disgrace to the South-Eastern Railway and one for which the directors should be called to account by the Board of Trade. It was the worst specimen of gross and culpable mismanagement short of actual loss of life which could well be conceived, and it was a marvel that many were not swept off the platform and killed or injured by the approaching train. A holiday crowd of any class will push and struggle to gain their end, and the lower down in the social scale the crowd may be the keener will the struggle be. And a railway company should be compelled to take at least reasonable steps to prevent accidents and probable loss of life. We have very grave doubts whether the excursions promoted by the Sunday League are not extremely harmful. It cannot be good for men or women and still less for children and infants to spend some five hours in a crowded train and to be rattled over a badly laid road in an inferior carriage for the sake of spending a short time at an overcrowded seaside resort. The Sunday League would do better to transfer its subscriptions to one of the genuine agencies which exist for giving children and other workers a holiday in the country of decent length.

CANADIAN MEDICAL ASSOCIATION: VANCOUVER MEETING.

THE meeting of the Canadian Medical Association will take place on August 23rd, 24th, 25th, and 26th at Vancouver, British Columbia, under the presidency of Dr. Simon J. Tunstall. Vancouver has a splendid harbour, has wonderfully grown since 1886, and is the western terminus of the Canadian Pacific Railway. At the opening meeting on August 23rd at 10 A.M. Mr. A. W. Mayo Robson will deliver an address on Surgery and Dr. C. E. Dudley will deliver an address on Gynæcology. There will be numerous papers read by men prominent in the profession from Eastern Canada, the United States, and Great Britain. The entertainment committee has made arrangements so that the ladies accompanying the parties will be well provided with entertainments during the time the meetings are in progress. On August 25th an excursion will be made to New Westminster, the former capital of the province, 15 miles from the mouth of the Fraser River and one of the termini of the Canadian Pacific Railway, and a visit will be paid to the Asylum there; thence boat will be taken to Steveston to see the salmon canning. On August 26th steamer will be taken across the strait to Victoria, the capital, on Vancouver Island, where a garden party will be held at Government House, and in the evening a reception will take place at the Parliament Buildings. On August 27th those who desire will have an opportunity of visiting Williams Head Quarantine Station and Esquimalt, called the "Gibraltar of the Pacific Coast," a few miles north-north-west of Victoria. Arrangements have been made for excursions to Kaslo, on Kootenay Lake, and to Golden, and for those who wish to go further north special rates may be secured to Port Simpson by Dixon Sound, to Atlin in the neighbourhood of the Chilkoot Pass, and to Dawson for the Klondike region. Those going from eastern points who wish to avail themselves of the special rates are advised to forward their names to Dr. George Elliott, general secretary, 129, John-street, Toronto.

THE PROHIBITIVE PRICES OF WINES AT HOTELS.

FEW who know the routine life of hotels will be surprised to learn that their receipts are very sensibly diminishing in spite of the fact that the number of visitors is not appreciably less. The situation is perhaps to be explained by the heavy charges made for wine, which are the less justifiable because the bottle for which a high price is charged rarely contains even a sound wine. Red wines are seldom good at a hotel; sparkling wines may, as a rule, be trusted because the labels are the original shipper's, but they are sold at a price about 100 per cent. or more over the merchant's price. The visitor may to some extent escape such fleecing by ordering a bottle of good matured whisky and drawing upon it as he requires, mixing it with mineral water, or with plain water when the charge for the former happens to approach the sum of a shilling. It is much to be deplored that people who prefer the agreeable stimulating qualities of sound wine should be forced to get its mere alcohol equivalent in ardent spirits. Yet spirit drinking at meal times at the hotel is now the rule, as a glance round the dining-room will instantly show. There is no more agreeable or wholesome accompaniment to dinner than a sound, soft, non-acid, and light claret, and for such most wine drinkers would pay a reasonable price. If, however, they are inclined to choose something better than a mere *vin ordinaire* they know from experience that it will cost at least from 6*s*. to 12*s*. a bottle and its taste may throw doubt on the label. Sound vintage clarets may be purchased through a wine merchant at from 2*s*. to 4*s*. a bottle. In defence it is said that without big profits on the wines hotel keeping would not pay. We do not believe that a hotel cannot be run on successful lines without inflicting upon its *clientèle* exorbitantly expensive wines, and we are glad that the public attitude seems to be the one that is likely to produce a change. The man who has a wholesome preference for good wines and who generally eschews spirits should not be compelled to take refuge in the latter because of the unreasonably high charges for the former. Many hotels complain that their business is only done in seasons, in fits and starts, and therefore in these seasons they must reap their harvest. Their season, we are sure, would be a more enduring one if they would supply good wines at reasonable prices.

A VISIT OF FRENCH MEDICAL MEN TO LONDON.

THE arrangements for entertaining our French medical and surgical *confrères* who hope to visit us at the commencement of October have advanced in several directions since we last referred to the subject. Our visitors will be entertained at a dinner to be held at the Hotel Cecil on Oct. 12th. Sir William Broadbent, the chairman of the executive committee in London, will preside, and the French Ambassador, who was invited to be present but who will be out of town at that date, will be represented by M. Daeschner, First Secretary of the Embassy. The Hospitals Medical Society of Paris at its meeting held on July 8th accepted with pleasure all the items of the programme drawn up by the London organising committee and expressed its intention of doing everything in its power to make the visit successful.

JUVENILE SMOKING.

A BILL for the prevention of juvenile smoking has been presented in the House of Commons by Mr. R. Rigg and is supported by Colonel Bain, Mr. C. P. Allen, Mr. Cathcart Wason, Dr. Macnamara, and Mr. G. Lambert. The chief clause is as follows: "No person under the age of 16 years shall smoke or use tobacco in any form and any such person so doing shall be liable on conviction to a penalty not exceeding 10*s.* for each offence." Another clause forbids anyone to sell, give, or supply tobacco in any form to or for the use of any person under the age of 16 years and provides penalties for such an offence, the onus of proof of age to lie on the person charged with a breach of provisions of the Act. We give the promoters of this Act every credit for wishing to stop what is undeniably a danger to the health of the community—even though it be a much exaggerated danger—but we feel compelled to ask them how they are going to see that the provisions of the Bill are to be carried out? How for instance will they stop the street Arab from picking up "fags" and smoking them, and how is the unfortunate tobacconist to be sure that a customer is over the appointed age? Supposing again that a street boy is caught smoking, is charged and fined, who is to pay the fine? If his parents or guardians can be found they may be mulcted, but this will not affect "the soaring human boy" in the least, and should his father incontinently flog him the result will probably be a summons for assault. The Bill as drafted appears to us to be well-meaning but futile.

THE NATIONAL SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN.

THE annual report of this society has just been published and contains certain interesting particulars of its work and of its requirements. We learn from it that while the number of cases investigated exceeds that of last year by 2544 the prosecutions have been fewer by 135. It may be noted by any who may still entertain doubts as to the necessity for the work done by this society that in 556 cases children died from the cruelty to which they had been subjected. 56 new centres have been opened by the society. The financial record is a somewhat anxious one. There is a deficit in the year's account of £4818 and for the first time in seven years there has been a decrease in income which is £1301 less than that of last year. On the other hand, it is encouraging to find that the amount derived from annual subscriptions has increased by £566. The average cost per child is also less than formerly. Originally £1 4*s.* 2*d.*, it had fallen to 13*s.* 5*d.* last year and it is now 13*s.* The deficit referred to above is largely due to extension of the society's operations. We should be sorry to see any limitation of this work but it is obvious that sooner or later a want of funds must lead to diminished energy unless the public generally and members of local branches more particularly will see to it that money is forthcoming. It is hardly to be expected that the parent society can without public assistance fully supplement the resources of the ever-widening circle of its offshoots. There is no need for us again to commend the work itself. The existence of cruelty undoubtedly widespread and deliberate is its justification; its success and the respect, even the esteem, in which it is held among the class which it is intended to control form a gauge of its quality.

ARRANGEMENTS are being made to obtain special tickets at a reduced return fare for those who intend to be present at the Ophthalmological Congress at Lucerne on Sept. 14th and following days. Those who wish to avail themselves of the privileges afforded by the railway and steamboat companies to members of the congress should communicate at once with Mr W. H. Jessop, 73, Harley-street, W., stating in each case the number of tickets required. The purchase of these tickets does not involve travelling in a party and each member will be free to choose the day and train he may prefer.

THE Revaccination Bill which was presented to the House of Lords by the Duke of Northumberland and read a first time on May 16th was read a third time on August 5th, passed, and sent to the House of Commons. Its provisions are, shortly, to provide for the revaccination of children within six months of their attaining the age of 12 years. At this stage of the session it is, of course, hopeless to expect that the Bill will make any further progress.

WE regret to announce the death on August 9th from angina pectoris of Sir William Mitchell Banks. Sir William Banks built up a surgical reputation for himself in Liverpool which extended throughout the country. His Lettsomian lectures on Cancer of the Breast, which were published in THE LANCET early in 1900, will be remembered as some of his most recent work.

WE have also to announce the death on August 10th, at the age of 80 years, of Sir Frederic Bateman, consulting physician to the Norfolk and Norwich Hospital. His fame, like that of Sir William Banks, was not confined to the city in which he lived, but was widely spread in England and on the continent. We shall publish extended notices of the careers of both these distinguished medical men.

THE death is announced from heart failure whilst cycling of Dr. T. Gilbart Smith, physician to the London Hospital and to the Royal Hospital for Diseases of the Chest, City-road. Dr. Gilbart Smith was only in his fifty-sixth year and the news of his sudden death has come as a shock to many friends.

Dr. William Gayton, who will shortly cease to hold the office of medical superintendent of the North-Western Fever Hospital after 34 years' service under the Metropolitan Asylums Board, has been presented by his medical colleagues with a silver tea service on his retirement.

1901 CENSUS: GENERAL REPORT.

THE concluding volume of the reports of the Census of 1901 has been published in the course of the week. This report is signed by the Commissioners, Mr. W. Cospatrick Dunbar, Mr. Noel A. Humphreys, and Dr. J. F. W. Tatham. Including appendices it occupies 375 pages and contains much interesting statistical matter. In justification of the lateness of its appearance the Commissioners explain that in addition to the magnitude of the work itself a number of unforeseen obstacles have from time to time arisen to prevent the completion of the final report as soon as was anticipated. They express the hope that the measures they have taken to insure accuracy will compensate for the delay in the production of the report and that the conclusions therein set forth will bear the test of reasonable criticism. Whilst fully appreciating the nature of the difficulties with which the Commissioners have had to contend, amongst which changes in the official staff have probably had a share, we think that in the present instance the delay, which the Commissioners state to have been unavoidable, is the less to be regretted because, with a few exceptions, the information contained in the report might have been culled from the census volumes already issued, it being simply a question of summarising facts scattered through the pages of some 50 county parts. After a rapid survey of the 191 pages of letterpress we have marked for notice a few salient points which seem especially interesting to our profession. For the rest we refer them to the report itself.

With the aid of the table of contents it is easy to recognise the order of arrangement of the report which is appropriately introduced by an interesting summary of census legislation during the past century. We note that instead of following the plan of distributing the census returns in three volumes it was decided, as more generally convenient, to publish the tabular matter of 1901 for each county separately, so that each county part should contain the whole series of census facts for the county and its various subdivisions. Accordingly, these parts were published as soon as they could be prepared in the order determined by their population; thus the part for the county of London, in which the particulars were given for more than 4,500,000 people, or about one-seventh of the population of England, was obtainable by the public in January, 1902, the part for Lancashire and Yorkshire following in rapid succession, the entire series being completed in February, 1903. The county parts were followed in April, 1903, by a volume of summary tables, being for the most part aggregates of the tables in the county volumes. In October of the same year there was issued an alphabetical index of the names of counties, boroughs, and other areas dealt with in the entire series of tables, together with their populations, and references to the pages in the county parts in which they may be found. The issue of the present general report completes the publications of the 1901 census.

Among the sections of the report which chiefly interest medical men is one on Physical Infirmities. Considerable skill and care appear to have been expended in the preparation of this section which contains a large amount of important information in no way derivable from the census returns. For convenience of description the physically afflicted are classed as follows: (1) the blind; (2) the deaf and dumb; and (3) the insane. Concerning the above-named infirmities the Commissioners remark that the machinery of an ordinary census is but imperfectly adapted to furnish the requisite particulars with that degree of accuracy which is essential for statistical purposes. It is because experience has impressed them with this conviction that they have abstained from entering into minute details which, had the data been more trustworthy, would have proved highly instructive and useful. In discussing questions concerning the relative prevalence of blindness the main difficulty lies at the threshold and consists in the adoption of a uniform standard to which all cases of blindness should be referred. What is "blindness"? is the important point to settle. The question has long occupied the attention of philanthropists in England and in other countries and the Commissioners think that those who may be responsible for the arrangements connected with the next census should take steps to obtain expert opinion as to what standard of vision should be held to constitute "blindness" and also to determine whether any additional methods should be adopted in order to obtain, if possible, more accurate returns of the number and condition of the blind. Similar remarks are applicable to the case of the deaf and dumb. For if the standard of "stone deafness" be abandoned in the case of those returned simply as "deaf" each individual must be left to adopt for insertion in the "occupiers' schedule" his own definition of what constitutes "deafness." The report contains numerous tables setting forth the numbers of the physically afflicted under each of the headings here specified. The proportion of blind persons in the population has diminished at each successive enumeration since 1851, in which year particulars of those afflicted in this manner were ascertained for the first time. It will, however, be noted that although the decrease in the proportion of the blind in the latest intercensal period was still considerable, yet the rate of decrease which had obtained between 1871 and 1891 has not been maintained since the latter year. During the decennium 1891–1900, as also in recent previous intercensal periods, there has been a decrease in the proportion of blind children in the country generally, and this lends support to the contention in the general report for 1891 that the decrease may be due to the more efficient treatment of purulent ophthalmia and other infantile maladies which may result in blindness. In this connexion there appears in the report a valuable paragraph showing the successive steps by which the "present position of matters relating to the blind" has been attained. To this paragraph we are indebted for much interesting information that is new to us, as it contains a categorical statement of the various statutory and other provisions by means of which amelioration in the sad condition of the physically afflicted has been affected.

Coming to that section of the report which deals with the insane the Commissioners seem to concur in the doubt entertained by their predecessors as to whether the value of the information relating to mental infirmities that may be obtained from the ordinary census schedules is sufficient to warrant the continued demand for such details at the hands of the English householder. It appears that in arranging the "occupiers' schedule" for the recent census, with a view to secure greater accuracy in the returns of the insane, a change was made by substituting the term "feeble-minded" for "idiot." This change was adopted as an experiment at the suggestion of persons officially concerned in the guardianship of the insane, who represented to the Commissioners that this substitution would certainly lead to greater accuracy in the returns, the term "idiot" being regarded as opprobrious and as likely to cause concealment of the truth. This substitution has doubtless resulted in the acquisition of more accurate returns concerning the number of insane children, but it has tended to the destruction of the returns as a means of comparison with similar data at previous censuses and this latter result the Commissioners greatly deplore.

AN OLD CHYRURGEON.

"THIS Book is in no way right but in Johannem Baxter hand, for he is the true owner of it. May ye 12, 1655." These words—"A damned cramp piece of penmanship as ever I saw in my life"—were written on the fly-leaf of an old worm-eaten volume which lay in the "twopenny box" of a London bookseller. The book was a collection of medical directions, formulæ, and aphorisms written by the once famous Nicholas Culpeper, "student in Astrology and Physick," and now that the methodical, and doubtless worthy, Johannes Baxter is no more we need crave no man's pardon for annexing, exploring, and enjoying its yellow, old-world pages. And indeed there is much therein recorded that is of more than passing interest and of the chief features none is more striking than the number of cures prescribed which became obsolete and discredited later, only to be rediscovered with much pomp and ceremony nearly three centuries afterwards. "Let his drink be water ...... boiled," for example, is a caution which was re-issued by the Battersea authorities only as recently as last month; and similarly, though we dare hardly claim that "the lungs of a fox beaten into powder" is a sovereign remedy for consumption—unless, indeed, the fox be tuberculous and inoculation is here foreshadowed—yet Culpeper must be allowed full credit for the following passage —

The character of Nicholas Culpeper as he stands self-revealed in his book shows him to have been of the proper professional stuff He is confident in his own powers, for at the outset he addresses his "Worthy Readers" thus —

> MY WORKS have merited such just applause in the world *though envied by some illiterate Physicians, that I am the more* confident to goe on doing that good which you have received by my former labours

And again he writes —

> I revised this Treatise of FEAVERS the Method of which was Galen s This I am confident, it containeth most excellent Truths

But he is not always so satisfied with himself or others in treating of the "*Mare or incubus*' (in modern terms, nightmare) he adds a note —

> I have been myselfe strangely troubled with this disease since the writing hereof and in a farre different manner from what here is written but the Margent is too small to hold the Story

And again, in discussing Melancholic he adds,

> Had this been to do again, I could have done it 10 times better

So, too, as regards others, though in his "Synopsis of Simples" he is an avowed Galenist, elsewhere we read —

> *Galen maketh great stir and so also doth Hippocrates, to prove two* sorts of Vertigo All Gallen s (*sic*) words may not be Authenticks no, nor Hippocrates his neither and neither Fuchsius nor myself were nor are so simple but we know

One feature about the book under discussion is the essentially personal tone in which it is written

> the same temperature? This then is strange "Let such as are *troubled with red faces abstaine from salt Meats Garlick Onions,* and Mustard, yea if he be a Welch Man or Woman he must abstain from roasted Cheese and Leeks, and that is Hell upon earth to them

These and many more *obiter dicta* show the friendly relations which existed between doctor and patient or nurse, only in more scientific writings on Arthriticalls, Renalls, and the like is a *more* impersonal attitude maintained On two points our author was well equipped for his profession In the first place, in accordance with Aristotle s dictum, he had experienced the evil in himself, for on one occasion only "much and vast expence of *Physicke" cured him And again he writes —*

> Have a care of trying quaint experiences it had once almost cost me my life in doing it upon mine own body

Secondly, he approached every question with an open mind Every means to the desired end was welcomed and judged on its merits Open air cures, water cures, anti toxins, homœopathy, allopathy, are all foreshadowed in his system, and we can see how Christian Science becomes in part defensible when we read the following extracts —

> *To Make Children s Teeth Cut*
>
> Besides all this I am of opinion that the tooth of a dead man hung about the neck of a child will do it far better than either I am not *determined to give my reasons at this time,* yet will I give you a very simile for it, the Tooth of a dead man born about a man instantly suppresseth the paines of the teeth as I have often found my selfe, when all other remedies have failed me, and if this be true why not the other?

Again, "of melancholie"—

> as love joy griefe etc, o eating of wicked and rest by these (!)

This last sentence, ascribing properties to food, which are usually confined to human beings, is typical of much of Dr. Culpeper's writing Herbs are talked of in this way—a special condemnation being reserved for onions and garlick "which be malignant"; and similarly when "meat" is *referred to as* "*hot* and *moist* " or "*cold* and *dry*" it is in a non culinary sense that the words are to be understood. Much of the language of the book is of course determined by the theories prevalent at the time and of these theories none was more prominent than that which ascribed all the ills of mankind to humours of various kinds and degrees, and when once the practitioner's task has been reduced to the formula ' Follow his humours," the prominence of dieting in the treatment follows as a matter of course Un*fortunately, medical science did not rest content with* dietings cordials cephaliques, and "induction of sneezing by Betany " In most cases bleeding is prescribed and one shudders to think of the patient of whom it is written "You must bleed him *often, because all* his blood is corrupted" Almost every complaint, "melancholick,' "fewver," what you will—is supposed to be amenable to this sovereign cure, and a climax is reached when bleeding of the nose (if not checked by the "smelling to a live toad ' or even less savoury substances) is to be stopped "by opening a veine in the ear!"

But we have not yet mentioned the weakest point in our old chyrurgeon s armour He styles himself "late Student in Astrology and Physick,' and it is evident from his writing that he thought the *former qualification to be not the less* valuable of the two "Oyle of Vervaine is medicinall for the Headache let it be gathered in the day and houre of Venus, the ascending fortunately" "For the Megrim (migraine) comb the head with a combe made of the horn of a Ram (I suppose it were best when the Sun is in Aries or at least when Mars is there); and this may doe it—for aught I know—if the disease lie within or without the skull" And again ' Both for this ' (a "second dayes" Ague) "and quotidian Agues I *have never missed* cure by giving only Cinquefoil, gathered in the hour of Jupiter, if it be possible, he being above the earth and truly I think it would be the better if the moon were aspected to him but I never observed it" "The right eye of a man or the left of a woman are under *the Sun the left eye of a man,* the right of a woman, are under the Moone"—which facts are emphasised as being of vital importance in curing "A Pin and Web in the Eye" But it is needless to multiply examples "Guess the rest from these," and from the "Signes of a Plague to Come"—chief of which are the "meetings of superior Planets, whereby not only the time but also the place where the Pestilence will most rage may be gathered as this Autumnall Pestilence of 1645 was by Mr Booker in his Almanack which was penned at Midsomer 1644" "But the learned in Astrologie may satisfie them*selves without me,"* he adds Only the layman reads such signs as have recently been manifested, "cold weather out of its season,' "dark and troubled aire," or "birds forsaking *their nests"*

We have travelled far since 1655 and astrology has been to the position of a rogue and a vagabond, but in its dicta were as the following racy advice as to taking an "earewig out of the Eare" —

Such statements provoke a contemptuous smile now, yet they were written by one who was in his own day the great successor of Hippocrates and Galen, who could pour contempt upon "our pitiful physicians" and on those who, "being ignorant of Astrology, cannot give a reason of the Physick they prescribe, a Parrot may be taught to be as learned," and who could write at the conclusion of *his* work, "Venitq salutifer orbi —Nich Culpeper"

THE FOLKESTONE CONGRESS AND THE SANDGATE SCANDAL

GENERAL propagandism is undoubtedly the main object of such congresses as that just held at Folkestone by the Royal Institute of Public Health Doubtless the members learn a good deal from each other. Life is short and there are so many phases to public health questions that no one has the time to master them all. Consequently it is an advantage to hear a summary giving the results of investigations that have been undertaken with more than usual care. The criticism the papers call forth are equally instructive. But though such discussions render the congresses in a measure self-educating, nevertheless their main usefulness is due to the impression they produce on the outside general public and its consequent reflex influence on legislature. The local papers give lengthy reports of the proceedings. There are festivities at which the leading sanitary reformers coming from all parts of the country meet and talk with the notable inhabitants of the town where the congress assembles. This is useful in regard to general questions such as the purity of the milk-supply, physical degeneration, the hygiene of schools, &c., but it is still more effective and fruitful if there happens to be some local grievance to which it is necessary to draw public attention. This was the case at Folkestone and it is satisfactory to note that the congress fully acquitted itself of its task in this respect. Evidently the most useful purpose to be served by the meeting at Folkestone was to help the local efforts that are made to do away with the so-called sanatoriums for the treatment of tuberculous patients at Sandgate. This is at once a local and a national question, and the discussion which arose on the subject, together with the resolution adopted, fully confirmed all that we have published in regard to Sandgate. Full freedom of discussion was allowed and this is proved by the fact that a speaker was permitted to declare that vaccination was the greatest fraud of the century and was supported by the medical profession because they made money out of it. It would have been easy therefore for anyone to have pleaded at least extenuating circumstances in favour of the Jones homes if it had been possible to say anything on that score. But no such attempt was made. The only effort made was to shield the boards of guardians from blame, and this not because the Jones homes were proper places to send paupers suffering from tuberculosis but simply because the guardians did not know of any other place. Then, again, at the meeting for the closure of the congress, when all the sections assembled in the Woodward Hall together with several members of the public, the resolution carried in the Section of Preventive Medicine was read out. This resolution, if applied, would render such places as the Jones homes impossible, yet no protest whatsoever was raised. The large and general assembly then voted unanimously that this and the other resolutions carried in the section should be handed over to the council of the Royal Institute of Public Health with the request to do all that is possible to carry out the desires expressed.

The Mayor of Folkestone was in the chair; other local authorities and notabilities were sitting round. The resolution, which had been seconded by the medical officer of health of Sandgate, was read out very distinctly. The Jones's homes are houses that form part of the main street of Sandgate and have no grounds of their own. But the resolution says that sanatoriums "should stand in their own grounds in an isolated position away from the general population." The Jones's homes are entirely dependent on the Jones family. These irresponsible persons may occasionally resort to the advice of a medical practitioner but there is no guarantee that they will follow such advice nor are their any means of compelling them to do so. The proprietors of the Jones homes have no professional standing or reputation to maintain. They are lodging-house or boarding-house keepers, free to accept or reject any advice that may be given. But the resolution carried in the Section of Preventive Medicine says that such homes should "be placed under the absolute control of fully-qualified medical practitioners." The congress was held within two miles of the Jones homes. The advocates or partisans of these institutions, if such exist, might have made themselves heard. Not a word in their defence was uttered. Nothing could be more conclusive. No better qualified and no more emphatic condemnation could have been uttered. There were members of the congress coming from all parts of the country who had studied the subject of sanatoriums for the treatment of tuberculosis both at home and abroad and there were others who, living at Folkestone or Sandgate, knew all about the local circumstances. It is from such an assembly as this that an emphatic and unanimous pronouncement has been obtained, and not a voice was heard, not a word was uttered, in defence of the Jones homes. What, it may well be asked, will be done in response to so striking a demonstration? The Local Government Board can surely no longer affect to ignore the question. The county council of the district must now feel that it is bound to exercise its powers to the uttermost, while the nation at large will awaken to the fact that, though foremost in so many matters of sanitary reform, England is behind several European countries in regard to sanatoriums for the treatment of tuberculosis. The Poor-law Guardians are said to spend £1,000,000 per annum merely for the treatment of this disease and yet some among them still send sufferers to the Jones homes. The debate at the Folkestone Congress has shown that something better than this can and must be done. Perhaps after all the Sandgate scandal will ultimately prove to have been a blessing in disguise, for it has forced the general question of popular sanatoriums for the treatment of tuberculous patients upon the public attention. After the pronouncement made by the Royal Institute of Public Health at the Folkestone Congress the whole problem must be taken seriously in hand.

Looking Back.

THE LANCET, *SATURDAY*, AUGUST 12, 1826

FOREIGN DEPARTMENT.

On the Traffic with Leeches. By Dr. Kunzmann of Berlin. (Hufeland's Journal der Pract. Heilkunde, March, 1826.)

The increased demand for leeches during the last 20 years, and the scarcity of them in France, America, and particularly in England, compared with the abundance of these creatures in Germany, Silesia, and Poland, has gradually given rise to a trade with these animals, which is much greater than one would at first sight be inclined to believe. How profitable this trade must be, may be learned from this fact; that Apothecaries in Paris and London find it to their advantage to send men from these towns to procure or cause to be procured these animals for their use, and to convey them to these capitals. This, however, is less remarkable when we consider that in the year 1819, the expense for leeches alone in the Parisian hospitals was 4,800 sterling. In the year 1823 it was nearly 7000 guineas. According to Sarlandiere the yearly sum paid for these animals, for the hospitals in France, is upwards of *one million and a half of francs*, or in English money £60,000! Not less than *seven million two hundred thousand of these animals* are annually sent to England. The merchants buy them in summer for 12 rix dollars (36 shillings) a thousand; in winter they pay 30 to 45 dollars; a price which they can very well afford to give, for according to Boehr's statement, a shilling or eighteen pence will be sometimes paid a piece in the shops of London.

The mode that the leech merchants transport the animals is different. Some make use of wooden vessels, which have been carefully cleaned with boiling water, and which must have contained neither salt, nor tobacco, nor the like. In this vessel from 2 to 3000 are placed without water. In 36 hours afterwards, and just before they are put into the waggon, one fourth part of the vessel is filled with water.

As the young animals attack the old, care is taken by the merchants not to put these two together. When the journey is not above eight days, the animals in general live, but if the period of their transportation exceeds that, the greater part of them will die. The mortality is still greater when the weather is warm, or there has been thunder.

Another set of people, particularly the French merchants, transport these animals in a linen bag, which has been well washed, without soap, however, and in order to avoid the bad consequences of shaking during the transportation, they carry them. When thunder comes on they thrust bag and leeches into any marsh they find on the way, but not in a running stream. When the place is at no great distance, they put into one bag as many as it can hold. The better way seems, however, to be that we have already adverted to, transporting them in small numbers in bags.

The great object of the above statement respecting the quantities of leeches used, is to show the probable danger there exists of the supplies of these animals being soon exhausted, and to propose measures to be taken to prevent such a dreadful event. The alarm, however, is unfounded; and if it were not, the plan proposed of bringing them all together in one large marsh, or in places constructed for them, would be much more likely to create a dearth of these animals sooner than double the present consumption.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

South Shields County Borough.—Dr. J. J. Boyd draws attention to the absence of powers for the inspection of coal mines on the part of the sanitary staff, and he suggests that owing to the lack of sanitary supervision coal mines may be instrumental in promoting the spread of enteric fever. During 1903 30 per cent. of the wage-earning males who were affected with enteric fever in South Shields were employed in coal mines, whereas only 8 per cent. of the male population over 15 years of age are thus engaged. These facts show, Dr. Boyd thinks, an undue incidence of the disease in miners. He has also noted instances of apparent personal infection among those working on the same "shift" in a mine. This is a subject well worth further study. As a rule there are, we believe, no provisions made for the disposal of excreta and each miner selects the most convenient spot for the purpose, there being, however, an understanding that no spot immediately to the windward of the gang shall be [illegible] r. Boyd suggests, the recent [illegible] ankylostomiasis in our mines [illegible] y proper precautions should be taken.

Borough of Blackpool.—Dr. F. J. H. Coutts regrets the fact that many cases of pulmonary tuberculosis which are sent to Blackpool for the purpose of treatment are not in a stage of the disease for which this somewhat invigorating climate is suitable. Early cases of the disease in which there is no rapid breaking-down of lung tissue and where the general condition is good often do well in Blackpool but patients who are unable to stand the strong winds go rapidly to the bad. It is to be hoped that the medical practitioners who are in the habit of sending unsuitable cases may be warned by Dr. Coutts, as this indiscriminate treatment of all stages of pulmonary tuberculosis is much to be deplored on professional as well as humanitarian grounds. There was in Blackpool, as in the country as a whole, a slight incidence of enteric fever during 1903 and, in so far as Blackpool is concerned, Dr. Coutts is inclined to ascribe part of the reduction to the "oyster scare" which operated partly in preventing the eating of oysters and partly by making oyster merchants more careful as to the source from which their wares were procured. Moreover, in Blackpool the mussels which formerly were potent for harm have been stripped from the sewer outfall pipes and from the piers and taken out to sea. Unfortunately the cockles and mussels sold in Blackpool are procured from other sources which, judging by results, are by no means free from the risks of specific contamination. We shall all agree with Dr. Coutts in his desire that shell-fish should be under better control. Watercress also appears to have spread enteric fever during 1903 and there is no doubt that this is another raw food which requires more control.

Borough of Macclesfield.—The education committee of this borough has appointed Mr. J. Hedley Marsh, the medical officer of health of Macclesfield, to be its medical officer and a detailed survey of the schools and of their sanitary condition has already been made. In four out of the 16 schools privy-middens still exist. The medical officer is now engaged in an examination of the physical and mental conditions of the children with a view to ascertain *inter alia* whether any of the children are suffering from want of food or from injudicious feeding. As regards physica[illegible] ve been done already in Mac[illegible] the Macclesfield Patriotic [illegible] e years past instituted a sys[illegible] sical training.

Southall-Norwood Urban District.—In discussing the question of infantile mortality Dr. J. D. Windle expresses doubt as to the expediency of promoting a supply of sterilised milk. *Clean* milk does not, he thinks, require sterilising and he regards it as beginning at the wrong end to allow milk to get into such a condition that it needs sterilising. Such milk engenders, in his view, a false sense of security in that it only remains sterile "so long as it is stored with the strictest precautions against contamination." Here Dr. Windle hardly does justice to milk sterilised in bottles, as such milk if unopened will remain good for years. But notwithstanding this, there is much to be said for the view that a supply of fresh, pure, uncontaminated milk is the great desideratum of the present day. Both chemical preservatives and sterilisation tend in some degree to lead to carelessness in the matter of cleanliness and there are certain drawbacks to both methods of preservation, especially the former. All chemical preservatives in milk should, in our view, be absolutely prohibited. Dr. Windle thinks that it will be many years before the present Dairies, Cowsheds, and Milkshops Order provides us with pure milk and here we agree with him. Moreover, we are not indisposed to follow him in his somewhat heroic proposal for the establishment of municipal cowsheds and dairies, by which he understands "places where the housing of the cattle and the milking, collection, and distribution of milk for the purpose of infant feeding only would be carried out on scientific principles under official supervision, each dairyman paying his proportionate rent for the use of the premises." The idea is excellent but Dr. Windle goes perhaps somewhat beyond the bounds of discretion when he suggests that it should be illegal to sell milk for infant food from any other source. To place such a premium upon the milk of any given institution would be to destroy the private industry and a step such as this would invoke the hostility of the whole trade. Dr. Windle cannot have had much experience of legislative difficulties or he would content himself for the present with the establishment of the suggested models, leaving it to time to develop the idea.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 7740 births and 5785 deaths were registered during the week ending August 6th. The annual rate of mortality in these towns, which had been 13·7, 14·1, and 16·4 per 1000 in the three preceding weeks, further rose last week to 19·8 per 1000. In London the death-rate was 19·6 per 1000, while it averaged 19·8 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·5 in Southampton, 7·7 in Smethwick, 9·8 in West Hartlepool, 10·1 in Grimsby, 10·2 in King's Norton, 10·8 in Croydon, and 10·9 in Hornsey; while the highest rates were 26·3 in Stockport, 26·8 in Birkenhead, 30·7 in West Ham, 32·1 in Bootle, 33·6 in St. Helens, and 37·6 in Liverpool. The 5785 deaths in these towns last week included 2058 which were referred to the principal infectious diseases, against 506, 792, and 1255 in the three preceding weeks; of these 2058 deaths, 1750 resulted from diarrhœa, 118 from measles, 95 from whooping-cough, 46 from diphtheria, 20 from scarlet fever, 22 from "fever" (principally enteric), and seven from small-pox. No death from any of these diseases was registered last week in Hastings, in Tynemouth, or in West Hartlepool; while the highest death-rates from the principal infectious diseases were recorded in St. Helens, East Ham, Walthamstow, Birkenhead, Stockport, Aston Manor, West Ham, Bootle, and Liverpool. The greatest proportional mortality from measles occurred in Bradford, Rhondda, Birkenhead, Hull, and Bootle; from diphtheria in Bradford and Halifax; and from diarrhœa in Walthamstow, Bootle, St. Helens, East Ham, Stockport, West Ham, Aston Manor, and Liverpool. The mortality from scarlet fever, whooping-cough, and "fever" showed no marked excess in any the large towns. Of the seven fatal cases of small-pox, two belonged to Stockport, and one each to Gateshead, Liverpool, London, Manchester, and Warrington. The number of small-pox patients in the Metropolitan Asylums hospitals at the end of last week was 32, against 62, 51, and 46 at the end of the three preceding weeks; two new cases were admitted during the week, against seven, six, and seven in the three preceding weeks. The numbers of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 1698, 1754, and 1784 on the three preceding Saturdays, declined again to 1758 on Saturday last, August 6th; 166 new cases were admitted during the week, against 229, 234, and 243 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 155, 120, and 118 in the three preceding weeks, further fell last week to 112, but were five above the number in the corresponding period of last year. The causes of 48, or 0·8 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Salford, Bradford, Leeds, Sheffield, Hull, Newcastle-upon-Tyne, and in 52 other smaller towns; while the largest proportions of uncertified deaths were registered in Handsworth, Middlesbrough, Barrow-in-Furness, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 14·8, 15·7 and 14·1 per 1000 in the three preceding weeks, rose again to 14·6 per 1000 during the week ending August 6th, and was 5·2 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 9·1 in Leith and 11·8 in Paisley to 15·3 in Dundee and 23·1 in Perth. The 483 deaths in these towns included 48 from diarrhœa, 26 from whooping-cough, five from measles, three from "fever," two from diphtheria, and one from scarlet fever. In all, 85 deaths resulted from these principal epidemic diseases last week, against 53, 68, and 58 in the three preceding weeks. These deaths were equal to an annual rate of 2·6 per 1000, which was 4·4 per 1000 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of diarrhœa, which had been 19, 23, and 24 in the three preceding weeks, further rose last week to 48; 32 occurred in Glasgow, four in Edinburgh, four in Dundee, and four in Aberdeen. The deaths from whooping-cough, which had been 22, 21, and 19 in the three preceding weeks, rose again last week to 26, of which 15 occurred in Glasgow, four in Paisley, and three in Edinburgh. The deaths from measles, which had been six, 12, and seven in the three preceding weeks, fell last week to five; two of these occurred in Greenock. The fatal cases of "fever," which had been three, three, and four in the three preceding weeks, were three last week. The deaths from diphtheria, which had been two, three, and two in the three preceding weeks, were again two during the week under notice. The deaths from scarlet fever, which had been two, three, and two in the three preceding weeks, fell to one last week. The deaths referred to diseases of the respiratory organs in these towns, which had been 49, 75, and 55 in the three preceding weeks, fell last week to 47, and were seven below the number in the corresponding week of last year. The causes of 17, or more than 3 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19·3, 17·5, and 17·9 per 1000 in the three preceding weeks, further rose to 21·2 per 1000 during the week ending August 6th. During the past four weeks the death-rate has averaged 19·0 per 1000, the rates during the same period being 15·8 in London and 13·8 in Edinburgh. The 154 deaths of persons belonging to Dublin registered during the week under notice showed an increase of 24 over the number in the preceding week and included 25 which were referred to the principal infectious diseases, against 18, 15, and 12 in the three preceding weeks; of these, 15 resulted from diarrhœa, four from whooping-cough, three from measles, two from diphtheria, and one from scarlet fever, but not any from small-pox or "fever." The 25 deaths were equal to an annual rate of 3·4 per 1000, the death-rates last week from the principal infectious diseases being 7·1 in London and 1·7 in Edinburgh. The fatal cases of diarrhœa, which had been two, five, and four in the three preceding weeks, rose last week to 15. The deaths from measles, which had been ten, five, and four in the three preceding weeks, declined to three last week. The fatal cases of whooping-cough, which had been three, three, and two in the three preceding weeks, rose last week to four. Diphtheria caused two deaths last week against one in the preceding week. The 154 deaths in Dublin last week included 43 among children under one year of age and 37 among persons aged 60 years and upwards, each of these numbers showing a considerable increase. Five inquest cases and two deaths from violence were registered; and 48, or over 31 per cent., of the deaths occurred in public institutions. The causes of ten, or more than 6 per cent., of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING JULY, 1904.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·1 per 1000 of the population, estimated at 4,648,950 persons in the middle of the year. In the three preceding months the rates had been 5·1, 5·9, and 5·4 per 1000. The rates were considerably below the average in Paddington, Chelsea, the City of Westminster, Hampstead, Stoke Newington, the City of London, and Greenwich; while they showed the largest excess in St. Pancras, Shoreditch, Bethnal Green, Stepney, and Bermondsey. The prevalence of small-pox during July showed a marked decline from that recorded in the preceding month; among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in Finsbury, Shoreditch, Bethnal Green, Stepney, and Camberwell. The Metropolitan Asylums hospitals contained 46 small-pox patients at the end of last month, against 104, 118, and 74 at the end of the three preceding months; the weekly admissions averaged eight, against 24, 23, and 13 in the three preceding months. Scarlet fever was more prevalent last month than it had been during June; this disease was proportionally most prevalent in St. Pancras, Islington, Hackney, Bethnal Green, Stepney, and Woolwich. The number of scarlet fever patients in the Metropolitan Asylums hospitals, which had been 1515, 1632, and 1599 at the end of the three preceding months, rose to 1764 at the end of last month; the weekly admissions averaged 241, against 173, 219, and 206 in the three preceding months. The prevalence of diphtheria last month showed a marked increase over that recorded in the preceding month; among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in Fulham, the City of London, Bethnal Green, Stepney, Poplar, and Deptford. The Metropolitan Asylums hospitals contained 763 diphtheria patients at the end of last month, against 718, 755, and 681 at the end of the three preceding months; the weekly admissions averaged 124, against 97, 113, and 95 in the three preceding months. The prevalence of enteric fever last month showed a small increase over that recorded in the preceding month; this disease was proportionately most prevalent in Hackney, Finsbury, Stepney, Southwark, Bermondsey, and Greenwich. The Metropolitan Asylums hospitals contained 67 enteric fever patients at the end of last month, against 62, 51, and 62 at the end of the three preceding months; the weekly admissions averaged 15, against nine, ten, and 12 in the three preceding months. Erysipelas was proportionately most prevalent in St. Marylebone, Shoreditch, Bethnal Green, Stepney, Southwark, and Bermondsey. The 20 cases of puerperal fever notified during the month included five in Southwark, two in Kensington, two in Battersea, and two in Wandsworth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in public institutions having been distributed among the several boroughs in which the deceased persons had previously resided. During the four weeks ending July 30th the deaths of 4856 persons belonging to London were registered, equal to an annual rate of 13·6 per 1000; in the three preceding months the rates had been 16·2, 13·9, and 12·5 per 1000. The lowest death-rates in London last month were 6·7 in the City of London, 7·2 in Lewisham, 8·6 in Hampstead, 10·2 in Wandsworth, and 11·2 in Greenwich; while the highest rates were 15·8 in Bermondsey, 16·0 in Holborn, 17·2 in Stepney, 17·7 in Poplar, 20·3 in Shoreditch, and 20·9 in Finsbury. The 4856 deaths from all causes in London last month included 900 which were referred to the principal infectious diseases; of these, three resulted from small-pox, 177 from measles, 28 from scarlet fever, 33 from diphtheria, 90 from whooping-cough, 16 from enteric fever, and 553 from diarrhœa. The lowest death-rates from these diseases were recorded in Paddington, the City of Westminster, Hampstead,

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JULY, 1904.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1904.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	Small pox.	Measles. * Including membranous croup.

Stoke Newington, the City of London, and Lewisham; and the highest rates in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, and Bermondsey. Of the three fatal cases of small-pox registered last month, two belonged to Finsbury, and one to Bethnal Green. The 177 deaths from measles were 14 below the average number in the corresponding period of the ten preceding years; among the various metropolitan boroughs this disease was proportionately most fatal in Islington, Finsbury, Bethnal Green, Bermondsey, Lambeth, Deptford, and Greenwich. The 28 fatal cases of scarlet fever were 24 below the corrected average number; the greatest proportional fatality from this disease occurred in St. Marylebone, Shoreditch, Bethnal Green, Poplar, Bermondsey, and Battersea. The deaths from diphtheria numbered 33 last month, the average number in the corresponding periods of the ten preceding years having been 137; among the various metropolitan boroughs this disease was proportionately most fatal in Hammersmith, Hackney, Shoreditch, Bethnal Green, Stepney, and Poplar. The 90 fatal cases of whooping-cough showed a decline of 49 from the corrected average number; the [illegible] mortality from this disease occurred in S[illegible], Shoreditch, Bethnal Green, Poplar, Lambeth, Greenwich, and Woolwich. The 16 deaths from enteric fever were 17 below the average number in the corresponding periods of the ten preceding years. The 553 fatal cases of diarrhœa were 81 below the corrected average number; this disease showed the highest proportional mortality in Hammersmith, Shoreditch, Stepney, Poplar, Southwark, Bermondsey, and Woolwich. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was over 24 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 140 per 1000. The lowest rates of infant mortality were recorded in Hampstead, Stoke Newington, Holborn, the City of London, and Lewisham; and the highest rates in Shoreditch, Stepney, Poplar, Bermondsey, and Lambeth.

THE SERVICES.

Royal Navy Medical Service.

The following appointments are notified:—Surgeons: A. R. H. Skey to Royal Marine Depôt, Deal; E. R. Grazebrook to the *Cambridge* for the *Undaunted;* R. St. G. S. Bond to Royal Marine Division, Plymouth; C. R. Nicholson to Royal Marine Division, Portsmouth; and A. Woollcombe to the *President* to be lent to Yarmouth Hospital. Surgeon and Agent: R. J. George at Port Isaac.

The following Surgeons have been promoted to the rank of Staff Surgeon: J. C. Durston and A. H. Jeremy, with seniority of Nov. 14th, 1901; R. S. Bernard and M. H. Knapp, with seniority of May 16th, 1902; and R. A. Ross, with seniority of Nov. 12th, 1903.

Royal Army Medical Corps.

The undermentioned Captains to be Majors (dated July 27th, 1904):—H. A. Hinge, J. G. McNaught, H. A. Bray, T. McDermott, E. W. Slayter, H. S. Thurston, L. P. More, C. O'C. Hodgens, Brevet Major A. F. Tyrrell, T. P. Jones, W. D. Erskine, A. G. Thompson, G. A. Moore, R. C. Lewis, R. F. E. Austin, H. W. H. O'Reilly, N. Marder, E. H. Condon, G. S. Mansfield, F. G. Faichnie, H. W. K. Read, and A. J. Chambers; (dated July 30th 1904)—F. M. Mangin, C. E. Pollock, W. J. Taylor, B. W. Longhurst, and J. H. Rivers.

Army Medical Reserve of Officers.

Surgeon-Lieutenant-Colonel J. G. Saville, having resigned his Volunteer appointment, ceases to belong to the Army Medical Reserve of Officers.

Volunteer Corps.

Royal Engineers (Volunteers): 1st Bedfordshire: Surgeon-Lieutenant G. H. Goldsmith to be Surgeon-Captain (dated August 6th, 1904).

Rifle: 3rd (Dumfries) Volunteer Battalion the King's Own Scottish Borderers: Surgeon-Liutenant G. R. Livingston is borne as Supernumerary whilst commanding the Scottish Volunteer Infantry Brigade Bearer Company (dated August 6th, 1904). 4th Volunteer Battalion the East Surrey Regiment: Surgeon-Captain W. H. F. Young resigns his commission (dated August 6th, 1904). 2nd Volunteer Battalion the South Staffordshire Regiment: Cyril Stephen Stokes Rigby to be Surgeon-Leutenant (dated August 6th, 1904).

Royal Army Medical Corps (Volunteers).

Welsh Bearer Company: Brigade-Surgeon-Lieutenant-Colonel C. Downing is seconded whilst holding the appointment of Senior Medical Officer to the Welsh Volunteer Infantry Brigade (dated August 6th, 1904).

The New Army Scheme.

Mr. Arnold-Forster took advantage of the occasion of the House going into committee on the Army Estimates on August 8th to make a long supplementary statement as to the nature and extent of his proposals regarding army reform. This was in further elucidation of the scheme which he had previously brought forward. In the discussion which followed the new proposals were somewhat severely and on the whole adversely criticised, the opposition strongly protesting against any advantage being taken of their vote on that occasion by construing it as expressing any approval on the part of the House of the new scheme as a whole. Apart from the extremely difficult nature of the problem in itself Mr. Arnold-Forster had to effect at the same time a financial saving. This he proposes to do by lopping off much useless and redundant material—as far as war service is concerned—for which the nation is paying, and by improving the quality and practically increasing the efficiency and availability of what remains.

One great difficulty which confronts our war ministers is the provision of long-service men for duty in India and the colonies. The nation has to garrison India and the great coaling stations, and three-years' men are ruinously costly for this work. The proposal is to divide the army into two—a long-service force for foreign duties, the men serving for nine years with the colours and three with the reserve; and a short service army of two years and six in the reserve for home duties but available to go abroad in case of war. Out of the long-service army there would be provided a striking force ready to go anywhere on the shortest notice. The idea is, no doubt, a rational and good one and looks well on paper, but would it work in practice? And, short of an experimental trial, how can this be determined?

We said on the occasion of the first appearance of Mr. Arnold-Forster's scheme that it had its good and bad features as well as much that was, and must be, of a tentative and provisional nature, and this seems to have been the opinion of the House of Commons. The new measure is so bold and comprehensive and potent for good or evil that it is only natural there should be pronounced hesitation before adopting it. The short home service army would probably be popular and attract recruits, but it is not so clear that the long foreign service army would do so. We should by long service to some extent probably lessen the amount of enteric fever which proves such a scourge to our troops serving in India. Mr. Arnold-Forster apparently altogether sets aside compulsory service as not only impracticable in the present state of public feeling but as, for financial reasons, prohibitive. For our part we look forward to the time when this country, acting in connexion and taking counsel with her colonies and dependencies, will frame some scheme for the organisation of an imperial army.

Royal Army Medical Corps Examination.

The War in the Far East

The principal matter connected with the war in the Far East which is at the present time absorbing attention in political circles in this country is not so much the progress of the campaign as the object and motives underlying Russia's action with regard to her volunteer fleet and the possible result of that action as regards ourselves The question which many people are putting to themselves is this Whether Russia is seeking to bring about a rupture *with this and another country to save her loss of prestige in* the event of her having to withdraw from Manchuria and confess herself defeated by Japan ?

Be that as it may there is a comparative lull in the war news at the present time—the issue of the campaign still hangs in the balance the decisive battle so often spoken of as imminent with Kuropatkin's forces has still to come off, and Port Arthur yet holds out The weather at the seat of war has for this season been exceptionally dry and hot, the heat having vastly increased the labour and fatigue of the troops in the field and given rise to a good deal of sunstroke and heat exhaustion The Russian soldiers have been heavily pressed by frequent fights and dispirited by numerous defeats and retreats It need scarcely be said that troops habitually finding themselves numerically inferior to their enemy and frequently having to yield positions because of their being capable of being turned are very apt to lose their nerve But it is in such circumstances that the stolid fortitude and obduracy of the Russian soldier show to the greatest advantage and never more so perhaps than has been the case in the present war We may set aside the enormous estimated losses on the part of the Japanese in their assaults on Port Arthur as at least *untrustworthy exaggerations but there can be no doubt that* their losses on these occasions have been considerable and that the capture of Port Arthur has proved, and is still proving a much more difficult undertaking than has been generally represented The advent of heavy, rains which if delayed must nevertheless occur and the delay which has taken place on the part of the Japanese armies in attacking the Russians and cutting off their line of communication with their base, are all in favour of the latter In the retreat of the Russians from Haicheng the wounded in the fight of July 31st were quickly placed in the hospital train and the Red Cross Society is said to have displayed great rapidity in dealing with them Many of the unfortunate soldiers were terribly wounded by shrapnel

The statistical calculations which have appeared in Russia regarding the casualties from wounds and sickness in General Kuropatkin's armies are not to be relied on but so far as they go they do not indicate anything exceptional in the circumstances There seems to be a very disproportionate rate of sickness and mortality among the officers as compared with the men of the Russian army probably attributable to the fact that the mode of life and training of the men render them better fitted to endure the privation and hardships of campaigning The sick are mostly suffering from dysentery After the beginning of the rains (from June 13th) the proportion of wounded and especially of sick casualties greatly increased The *Journal*

' month contains an

ices in the Russian

R A.M C (retired)

The *Novosti*, in an article entitled The War Doctors and Jews, insists on the necessity of cancelling at all events for a time the rule restricting the admission of Jews to medical education It points out the valuable services the Jewish medical men have rendered on the battlefield *and states further that* at a time *when the number of Jews* accepted for the medical faculty in the universities does not exceed from 3 to 10 per cent , and is reduced to *nil* in the Military Medical School, we find that in Kharbin alone there are 45 Jewish military medical men and that these constitute over 50 per cent of all the medical men to be found there The population of Russia is sorely in want of all kinds of medical assistance, be it by Russian, German, Jew, Buriatt, or other , therefore it is not in the interest of the people to limit the supply As to keeping in Russian hands the practice that would otherwise fall into the hands of the Jews it has been clearly shown that although the medical career is wide open to Christians these quite fail to satisfy the wants of the immense Russian population The medical profession should be thrown open to all, and even then *many years will be necessary to educate the required* number Such a step is requisite to inculcate suitable ideas of hygiene amongst the Russian masses, who are at the mercy of quacks and pretenders to mystic knowledge and sorcery and, on the other hand there is really no valid reason for hindering such a development

THE BISHOP OF LONDON'S URGENT APPEAL ON BEHALF OF HIS DIOCESAN BOYS' CAMPS

To the Editors of THE LANCET

SIRS —I hope that the numerous appeals which I have been obliged to address to the public this summer will not prejudice the one which I now make on behalf of our London boys I am writing this surrounded *by 300* happy boys, some bathing some playing cricket, others acting as sentry and guarding the camp and all trained and invigorated by a week at the seaside and the healthy activities of camp life These boys return to morrow morning to be succeeded by 600 more, who will arrive for their week in the afternoon

It would be impossible to imagine a more ideal holiday for boys after the confinement and monotony of their work in London, but although the boys all pay according to their wages, towards their outing a large sum is required for tents, the railway fares and the catering for so large a number and *for the first* time for 15 years we are face to face with a serious deficit I hope that I shall not appeal in vain for so successful and necessary a work Cheques should be sent to Mr F Abel Bloxam 23 Northumberland avenue, Charing Cross

I am Sirs yours faithfully,
A F LONDON

London Diocesan Seaside Camp for Working Lads,
Bexhill July 30th

NATIONAL LEAGUE FOR PHYSICAL EDUCATION AND IMPROVEMENT

To the Editors of THE LANCET

SIRS —In a leading article in THE LANCET of Jan 31st, 1903 p 315 you pointed out that the unfitness for military service to which Sir Frederick Maurice had called attention was not the condition of the population at large but only of a certain section of it In a letter to THE LANCET of Feb 14th 1903, p 471, I mentioned the fact that records were being constantly broken as supporting your position and as showing that the physique of some classes was improving rather than deteriorating At the same time I suggested the appointment of a commission to obtain information as to (1) the causes of physical deficiency (2) the best means of remedying the defects and (3) the best means at present available in case that the best means possible cannot as yet be applied ' In April, 1903, Sir William Taylor, Director General of the Army Medical Department, prepared a memorandum of the unfitness of a large proportion of the young men of this country for military service This memorandum led to the appointment of an Interdepartmental Committee on Physical Deterioration This name as Sir William Taylor remarks (Report of the Commission pp 2 and 100) is to be regretted, for it implies a comparison between the past and the present, and as no data exist for such a comparison it is impossible to come to any

Stoke Newington, the City of London, and Lewisham; and the highest rates in Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, and Bermondsey. Of the three fatal cases of small-pox registered last month, two belonged to Finsbury, and one to Bethnal Green. The 177 deaths from measles were 14 below the average number in the corresponding period of the ten preceding years; among the various metropolitan boroughs this disease was proportionately most fatal in Islington, Finsbury, Bethnal Green, Bermondsey, Lambeth, Deptford, and Greenwich. The 28 fatal cases of scarlet fever were 24 below the corrected average number; the greatest proportional fatality from this disease occurred in St. Marylebone, Shoreditch, Bethnal Green, Poplar, Bermondsey, and Battersea. The deaths from diphtheria numbered 33 last month, the average number in the corresponding periods of the ten preceding years having been 137; among the various metropolitan boroughs this disease was proportionately most fatal in Hammersmith, Hackney, Shoreditch, Bethnal Green, Stepney, and Poplar. The 90 fatal cases of whooping-cough showed a decline of 49 from the corrected average number; the greatest proportional mortality from this disease occurred in St. Pancras, Finsbury, Shoreditch, Bethnal Green, Poplar, Lambeth, Greenwich, and Woolwich. The 16 deaths from enteric fever were 17 below the average number in the corresponding periods of the ten preceding years. The 553 fatal cases of diarrhœa were 81 below the corrected average number; this disease showed the highest proportional mortality in Hammersmith, Shoreditch, Stepney, Poplar, Southwark, Bermondsey, and Woolwich. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was over 24 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 140 per 1000. The lowest rates of infant mortality were recorded in Hampstead, Stoke Newington, Holborn, the City of London, and Lewisham; and the highest rates in Shoreditch, Stepney, Poplar, Bermondsey, and Lambeth.

49 candidates entered and 14 of those who passed possessed university degrees.

and standard memoirs to considerable advantage, for anything in the nature of malice was far from the minds of those ideal hosts of the old school.

Sir John Simon sprang from a good French *émigré* stock that had taken to commerce in London and he was sent into the medical profession as so many of his neighbours were sent by merchant fathers too timid to venture to give their sons a university education and *yet unwilling to bring all their boys up to the counting* house. As long ago as 1833 he began the study of medicine under the famous Joseph Henry Green of St. Thomas's Hospital. The elder Greens and Simons both belonged to the City, but Joseph Henry Green, born on London Wall in 1791, was an idealist, as it were, escaping from mercantile associations, and young Simon was from the first strongly influenced by his tall, languid, dreamy master. Green was the intimate friend of Samuel Taylor Coleridge, who ended his opiated career in the house of Mr. Gillman, the Highgate surgeon, and was known also to Wordsworth. Simon in his "Private Recollections" tells with enthusiasm of a morning spent, by Green's introduction, with William Wordsworth, who read to him a sonnet. Simon and his fellow pupil and [illegible] the medical students of that far off day certainly furnished the then youthful Charles Dickens with the models for Bob Sawyer and Richard Allen. In the homes of their staid Puritanical elders the medical students of the "thirties" were apt to be regarded as savages—medicine men dealing in human bones and addicted to body-snatching and the abuse of tobacco. Quite lately Sir John Simon humorously confessed that in the house of my maternal grandfather he had been relegated to side doors and back stairs and rooms specially set apart. Such treatment implied no specific insult and no offence was taken by the young men themselves, but it is certain that Simon though he might have had the tobacco habit, in no other way resembled the medical students of Dickens or Albert Smith. These details of student life are trivial enough but now that Mr. Edmund Image, Mr. John Birkett, and Sir John Simon, the three senior *Fellows of the Royal College of Surgeons* have all passed away within a year we shall hear them from few, if any, living lips.

Simon's general culture advanced apace. He travelled extensively in the home countries of Europe and at an early date became familiar with many notabilities in France and Germany. He spent a day with Liebig as he had spent one with Wordsworth. In Berlin in 1841 he enjoyed the conversation of Ludwig Tieck and his brother the sculptor, of Rauch the sculptor, Waagen the art curator, and so forth. At Dresden he visited Retsch, the illustrator of "Faust," and at Munich discussed philosophy with the great Schelling. He expresses his pleasure at having seen and heard Felix Mendelssohn in London. He paid no visit anywhere, in fact without gaining an insight into all that was best in the artistic and literary life of the place *visited*. Yet he never forgot his own proper business of science, for at an early age he made the acquaintance in his travels of Vrolik, Schröder von der Kolk, Flourens, Tiedemann and Henle and continued throughout life this custom of adding to his circle of friends all that was most *eminent* in the surgical and *medical* science of Europe and America.

We must not forget to mention two studies which if pursued might have led astray from science one whose leanings were essentially literary. When Simon was giving *anatomical demonstrations in the then very insanitary* dissecting [illegible] during mon[illegible] particularly [illegible] strongly to [illegible] of esoteric wisdom. Simon with medical friends and others formed themselves into a society for the study of German metaphysics. What he drew thence it is hard to imagine—certainly not the pellucid literary style in which his famous "Reports," his treatises, his polemical letters to the *Times*, and his numerous articles are so happily couched. He aimed, as we know from himself, at clearness, at perfect lucidity, the perfect expression of the thought in his mind, for beauties of style as such he cared naught. Yet Simon's balanced old world style is beautiful and remains a monument of English at its best. The style was, indeed, the man and it is scarcely paradoxical to say that without it Simon would not have been the great hygienic and social reformer that he was. With it, incidentally, he made sanitary reform a branch of English literature. There are certain passages in Simon's "Sanitary Institutions," a book that deserves to be read side by side with his friend Buckle's [illegible]" on which any student of English [illegible]ief among these is the whole grand [illegible] Francis of Assisi and the Franciscan Order, which begins on page 49 of the "Introduction."

I am, Sirs, yours faithfully,

Victor G. Plarr,

Librarian of the Royal College of Surgeons of England.

August 2nd, 1904.

THE USE OF PHENYLHYDRAZIN IN THE CLINICAL EXAMINATION OF URINE.

To the Editors of The Lancet.

Sirs,—It is with much interest and not a little regret that I have read in The Lancet of July 23rd, p. 211, Dr. W. H. Willcox's article on the above subject. My object in replying is simply to uphold the delicacy and accuracy of the test in question, for this is my sincere conviction—a conclusion arrived at after nearly seven years of patient labour. It would, indeed, be deplorable if some of your readers, influenced by Dr. Willcox's article, should be induced to abandon what has been proved one of the most reliable tests that we possess. No doubt some experience is necessary not only in the mode of its application but also in interpreting the results.

I will briefly endeavour to show that the attack on the merits of this method of identification of glucose in the urine has been made upon an erroneous basis—to wit: 1. The test as applied to the urine was originally proposed by Professor von Jaksch and was never intended to be used subsequent to hydrolysis of the urine by hydrochloric acid. 2. Dr. Willcox shows by his own experiments that normal urine when treated by the test in question does not yield characteristic crystals. 3. It is quite possible crystals were obtained from urine after hydrolysis with hydrochloric acid similar to those obtained from diabetic urine; but this is altering the condition of things. A test is only of value when applied under certain conditions. 4. Supposing the crystals obtained after hydrolysing the urine are similar in appearance to those obtained from diabetic urine, the melting point will not be the same unless the hydrolysis produces glucose from some as yet unknown substance or substances.

It follows, therefore, that the mere production of apparently identical, or even identical, crystals obtained under altered conditions does not in any way detract from the merits of the test. The experiments of Dr. Willcox are of much interest inasmuch as they show the possible existence of other substances in the urine not yet recognised.

I am, Sirs, yours faithfully,

A. F. Bilderbeck Gomess.

Drayton-gardens, S.W., July 31st, 1904.

THE PLAGUE IMMUNITY OF THE CITY OF MADRAS.

To the Editors of The Lancet.

Sirs,—In your leading article in the issue of June 18th, on the subject of "Immunity from Plague enjoyed by Shanghai," you remark that a similar immunity of Madras "is not understood." As this is not the first time that this subject has been referred to by professional papers it may be of interest to some of your readers to know what at least are certain of the factors concerned in bringing this protection about. I quite agree with you in thinking that there is nothing inherent in Madras to protect against this disease. Sanitary conditions and the death-rate which results therefrom are phenomenal. Before, however, I proceed to state why I consider the disease has been kept at bay I should like it to be understood that I am perfectly aware that, in dealing with a free population, no method of prevention is infallible. And even when recognising the merits of any special method it is necessary also to remember that in respect of plague as of any other infectious disease, it does not follow that, because one or more cases are introduced in a population, an epidemic *must* ensue. The conditions under which the morbific agent may be required to exhibit spread or duration of vitality may not be favourable, a small fact well worth remembering in fighting plague. The sanitarian may, with confidence, apply the principle that every chance of success is of solid advantage to him, and may remember that favouring accidents or chances affecting the disposal of infectious matter need not always be with the enemy.

When plague made itself felt in Hong-Kong in 1894 I issued a circular to port medical officers warning them of its possible entrance to this presidency. The moment it was ascertained that plague had entered Bombay, instead of adopting a system of quarantine and observation in camps I at once advised local bodies to employ passport surveillance of the type contemplated by the Local Government Board in England with reference to cholera. This was subsequently legalised by the Madras Government using the Epidemic Diseases Act; so that, by taking advantage of the revenue system of village organisation, every village and town in the area of 141,726 square miles of this presidency became a centre of sanitary action and surveillance. All persons proceeding from towns or villages "notified" as infected are required to take passports binding them to undergo surveillance during ten days in whatever localities they halt at. The first actual advent of plague in the city of Madras was in October, 1897, and although, as a matter of fact, in this first experience there was neglect of one day in surveillance which nearly led to a disaster, the tracing of cases was due to the existence of the passport system in its yet incomplete and non-legalised form. Since then, in the city of Madras 67 cases of imported plague have occurred, of which 59 have been directly, and the rest indirectly, detected under this system. Last year 79,488 passports were registered and only 2 per cent. of the holders were *not* traced. The trouble involved up to date to the municipal staff must have been great, but so far as one could perceive the result has been of enormous benefit to the 500,000 inhabitants of the city of Madras. Necessarily, the system is far from infallible. Irrespective of the possible arrival of infected material there must at times be evasions in the case of persons from infected areas who may or may not be incubating plague, the chances always, however, being heavily in favour of their not being infected, as shown by the large average number of cases that pass through the period of surveillance before a single case of plague is detected[1]—namely, 5000. Indeed, that the passport system has materially diminished without removing absolutely the chances of infection of the city is shown by the fact that in April this year Madras went through a small outbreak of indigenous plague, in all probability as a result of an evasion of the passport rules. The actual origin of infection was never ascertained, although the most reasonable hypothesis was the native rumour that the first death was in the case of a person who had been in the infected area of Bangalore and had evaded the passport rules on arrival. The suspicious death was fortunately reported by an anonymous petition to the medical officer of health who was able to warn in time the district medical officer in charge of a suburb beyond municipal limits to which certain of the contacts adjourned. The result was that the contacts were traced and on all the usual measures being applied to the infected localities the disease was stamped out, but not until 11 cases had occurred in the suburbs and five in the city of Madras. Luckily rats did not get infected. Not one of the cases was of the bubonic variety; they were toxic, pneumonic, and intestinal—showing, I think, that the Madras environment is capable of nurturing a very virulent strain of plague. The diagnosis of the last pneumonic case—a contact of a previous pneumonic case—was bacteriologically confirmed by Lieutenant-Colonel Bannerman, I.M.S., the then superintendent of the King Institute, Madras. As, then, you have remarked, there is nothing in the sanitary condition of Madras *per se* that has hitherto effected its protection. The chief factor in bringing about that result has been the activity of the municipal staff in keeping persons from infected areas under surveillance, aided by the passport system.

As a result of this method of fighting plague *from the commencement* of danger of importation numerous imported cases in hitherto uninfected areas have been detected in all parts of the presidency. Following prompt action by local officers in these cases no spread has taken place. Errors of judgment or breakdown of methods have led to indigenous plague in certain districts. But it has spread very slowly, and instead of there being widely scattered areas infected throughout the presidency [illegible] coalesce consequent upon the yielding [illegible] areas, the curious result has been seen of plague being confined to the districts bordering upon the great centre—namely, the Mysore Territory, whence the infection is constantly imported and where the repetition of chances is consequently greatest. Year after year a gradual addition to the numbers of these districts has occurred and an advance towards the central and southern districts is at the present time threatened. It can scarcely be hoped that Madras city will escape being indigenously infected, but in the meantime the struggle by Government and local authorities in this presidency has been well sustained and the result has been, I think, to earn a grade of protection of life and trade that would not have been feasible had plague been "let rip."

I am, Sirs, yours faithfully,

W. G. KING,

Madras, July 13th, 1904. Lieutenant-Colonel I.M.S.

---

[1] In an indigenously infected district the examination of each 1600 passport holders arriving in uninfected areas secured one case of plague.—W. G. K.

LAYMEN AND ELECTRICAL TREATMENT.

To the Editors of THE LANCET.

SIRS,—In answer to Dr. E. Stanley Smith's letter in THE LANCET of August 6th, p. 423, I should like to bring before him the following considerations. First, the expense. I am sure that any medical man working at electro-therapeutics would willingly treat cases at whatever fee their medical adviser thought or knew they could afford. In suitable cases properly vouched for by their practitioner no fee for treatment in private would, I am sure, be charged. From what I know of the charges of my registered *confrères* I am of opinion that they would agree with me that, as a rule, skiagrams from £3 to £10 are the peculiar perquisite of the unregistered quack. I shall be pleased to send to any registered medical practitioner the list of the British Electro-Therapeutic Society, upwards of 200 medical men in London and the provinces, who would I am certain charge the fee that the medical attendant thought proper. Regarding the "absurdity of contending that there can be anything harmful to a patient in getting a layman to take a skiagraph," I would contend, Sirs, that it most assuredly depends on what the medical man wants. Does he want a picture? or Does he want to have skilled medical advice on the *interpretation of the skiagraph?*—things which, as you are well aware, are totally different in nature.

Again, we should be pleased to hear of the "layman," electro-therapeutic institute, &c., who, possessing a certain amount of elementary knowledge of anatomy, is still capable of knowing when to stop in treating any case with x rays, high-frequency, or any other form of electrical treatment. If this does not require a full medical training how is it that our hospital statistics are better than those of laymen or lay institutes? Why is it that the history of our hospital and, alas, often our private patients is very generally that they have tried this or that quack or quack institute and paid good fees before they come to us or our out-patient department for cure? This can be easily proved by a visit to any hospital with the requisite electrical department.

Secondly, regarding Dr. Smith's statement that "medical men shrink from sending their patients to another medical man owing to their diagnosis and treatment being overhauled by another," I would only ask the following question: Will the diagnosis and past treatment, good or bad, be upheld by a quack or quack institute rather than by one's own registered colleague?

Mr. H. Valentine Knaggs's letter in the same issue contains a somewhat alluring but dangerous suggestion. It is that medical practitioners who practise electro-therapeutics should *advertise* to obtain the support of some medical men and also to act as a foil to the numerous electrical quacks. This would entail de-registration. Does Mr. Knaggs seriously consider what this means to a duly registered medical practitioner? Would he give the same advice to the dermatologist, surgeon aurist, surgeon oculist, and laryngologist, or any other of our special practitioners? I venture to think, Sirs, that should we attempt to follow Mr. Knaggs's advice he would probably be the first to cast at us a stone.

Electro-therapeutics is recognised as a special branch of our art at all our large hospitals and most of the smaller ones and to all those who have carefully watched its development it comes somewhat as a surprise that any well-informed medical practitioner should for one moment be-little the assistance and help to medicine and surgery which the intelligent medical study of electro-therapeutics has already conferred.

I am, Sirs, yours faithfully,

Bedford square, W.C., August 8th, 1904. CHISHOLM WILLIAMS.

To the Editors of THE LANCET.

SIRS,—It is indeed sad to see how some members of the profession who love to pose as veritable models of light and leading in ethical matters, disregarding the General Medical Council's notice *re* "covering," still persist in countenancing unqualified practice by sending their patients to laymen for electrical treatment. The reasons suggested by Dr. E. *Stanley Smith in* THE LANCET *of August 6th, p. 423,* are at the best but poor and specious excuses for such [illegible] expense, squeamishness about [illegible] *ideas of treatment overhauled,* [illegible] knowledge of anatomy required [illegible] electricity.

A medical man who would rashly venture, on the score of expense, to send his patient to a "*skilled*" bone-setter, "*who has an elementary knowledge of anatomy.*" would, I fear, have a hard time [illegible] operative surgeons of his [illegible] principles. So likewise do [illegible] something other than "*abs*[illegible] *be anything harmful to a patient in getting a skilled layman to*" examine "*him* for diagnostic purposes." A correct diagnosis is the only sure basis of rational treatment. A patient who can afford to pay a fee of 30 to 100 guineas for a single operation can well spare an additional two or three guineas for an expert's opinion that will clinch the diagnosis in a doubtful case. Again, a skiagram is no more a measure of the exact value of a medical radiographer's services than a bottle of physic is of that of the [illegible] practitioner who dispenses. It is true that a certain [illegible] *of the public are imbued with this idea but, Heu pietas!* similar views are not held in professional circles. By those best fitted to express an opinion radioscopy rather than radiography is regarded as the surest guide to a correct diagnosis, although the latter has its uses for purposes of localisation and as confirmatory evidence in a court of law. It may easily be inferred from what has been already said that a skiagram is only a record of one phase of an examina- [illegible] mount of [illegible] a search [illegible] *ven more* experience is needed to tell which surface of the body or part was in immediate relation with the plate. This being the case, surely a labourer is worthy of his hire.

A great and wise physician has said, "We can learn a lot by our very mistakes, and none but a conceited ass would allow vanity to stand in the way of knowledge." Thank goodness, the profession at large are not to any extent afflicted with this troublous complaint, which spells death to consultations between medical men, whether specialists or general practitioners. How much reliance can be placed on "*the 'skilled' layman who has an elementary knowledge of anatomy*"? Is he likely to prove the superior of the average medical student in this respect? It cannot be too strongly emphasised that something more than a thorough acquaintance with the working of electrical apparatus and an elementary knowledge of anatomy is essential to success in electrotherapy. Experience that combin[illegible] the physiological and [illegible] and mastery of electrica[illegible] us in making a judicious selection c[illegible] the exact combination that will [illegible] ordinary knowledge of disease o[illegible] his cases to the skilled layman, who has a sound knowledge only of the workings of his apparatus, cannot supply this deficiency. Experience, which is a staff to the hand of the wise, is a rod for the back of fools. Unfortunately, in this case the punishment is too often administered by proxy, as it is the patient who suffers both in health and pocket for the *selfish considerations which prompt his medical attendant to* suggest this unethical course.

I am, Sirs, yours faithfully,

Leytonstone, Aug. 9th, 1904. CLARENCE A. WRIGHT

FREE OPERATIONS.

To the Editors of THE LANCET.

SIRS,—Your excellent special article on "Medicine and the Law" in THE LANCET of August 6th, p. 419, reminds us that in the case in question Miss Thorne operated without fee or reward, and has now been recompensed by the anxiety of a trial and the unpleasantness of a verdict against her. Was this patient really a case deserving of free operation? Would she not have been able to pay a moderate fee either to a London operator or to one of the excellent surgeons in the town from which she came? I am sure most provincial surgeons could give instances of well-to-do patients who have got operations done free in metropolitan hospitals or nursing homes and whose object in leaving their own localities was to escape the payment of surgical fees. Can any argument be advanced to justify this state of things? *Probably it is due to the* overcrowded state of the special departments of the profession in metropolitan cities and the desire of junior practitioners to gain experience, but that does not make it right. In some cases it is an abuse of hospital funds subscribed to benefit the deserving poor. In all cases it is an abuse of the charity of the medical profession and an injustice to provincial surgeons. Surely every possible care should be taken to separate the undeserving and often ungrateful from the really poor.

I am, Sirs, yours faithfully,

Belfast, August 8th, 1904. JOHN CAMPBELL.

THE INSURANCE OF MEDICAL MEN AGAINST THE DANGERS OF THEIR PROFESSION.

To the Editors of THE LANCET.

SIRS,—The first part of the letter which appeared in THE LANCET of July 30th, p. 327, signed by Mr. John [illegible] mis-statement of fact that calls for [illegible]. The subject of misrepresentation when raised by my counsel was at once objected to by the counsel representing the Scottish Accident Company and the objection was upheld by the arbitrator who said that it was not material to the matter under arbitation, which he further explained was limited to the terms of the policy which constituted the contract between the parties to the suit. I was therefore precluded from calling evidence on this point, although the agent, Mr. Croucher, was present in court. The bias underlying the entire letter is so self-evident as to relieve me of the necessity of dealing with any other of the points raised.

I am, Sirs, yours faithfully,

Guy's Hospital, S.E., August 5th, 1904. JNO. EYRE.

THE REPUTATION OF SIR EVERARD HOME.

To the Editors of THE LANCET.

SIRS,—The reputation of Sir Everard Home is severely dealt with in an annotation in THE LANCET of July 23rd, [illegible] t himself hopelessly [illegible] SS. *of John Hunter* [illegible] ircumstance that he did this just after publishing a large work of his own and after his co-executor, Dr. Matthew Baillie, had left London gives to the act a worse complexion. But strict justice must be claimed for every offender, and I ask, Is it fair to write, *apropos* of John Hunter's MSS., that "the windbag Home owed all his knowledge and reputation to them and became F.R.S. and Hunterian lecturer on the strength of them"? [illegible] was *Hunter's brother-in-law, his pupil from 1772, his* [illegible] executor, and he wrote an excellent and appreciative [illegible] f Hunter the year after his death in 1793. The best account of Home that I know is that given by Sir Benjamin Brodie in his autobiography, a little work which is a pattern of candour and right feeling. Brodie was a pupil of Home (1803) and later his assistant, continuing for a number of years to work with him in dissections, in comparative anatomy, &c. He therefore knew him intimately, and yet being himself connected with Matthew Baillie through the Denmans, and constantly working with Clift, Brodie was also in touch with other custodians of John Hunter's fame. The dispassionate in different places showed a different incidence under the same conditions, this was due partly to the presence of different quantities of tubercle bacilli but also to differences in predisposition of the population. From the year 1890 they began in Prussia really to fight against tuberculosis by making laws, by-laws of the sanitary police, and orders and instructions, especially for working men. Conradi and Koch believed that the decrease of tuberculosis in Prussia was caused by these measures, especially from the compulsory use of spittoons in public places, workshops, industrial establishments, and so on, but the sanitary officers and industrial inspectors reported that the working men did not pay enough attention to the orders; they did not make use of the spittoons and so prevented the destruction of the excreta. The decrease of tuberculosis really began in Prussia in 1880 —i.e., *ten years before the beginning of the anti-tuberculosis crusade* (1890), and in Bavaria about 20 years before that, in 1870, so that the new orders and instructions could not be the chief reason of this decrease, and the decrease was the same in agricultural districts where no special by-laws were made. In Germany in 1883 the great social laws were introduced for working men and the whole social condition was improved. By these laws pecuniary means were provided to fight against illnesses. The improvement of the social condition of all classes in the whole of Germany progressed with these new laws. Tuberculosis was chiefly an illness of the poorer people and attacked from four to six times more poor men than well-situated people. A great deal depended on predisposition and pre-existing disease weakened the resistance to tubercle. The fight against tuberculosis must be against infection, the disease, and predisposition. Infection was derived not only from man but also from warm-blooded animals. The infection of children from infected milk had been under-estimated by Koch, whereas Behring considered it of the greatest importance.

SECTION OF PREVENTIVE MEDICINE.

Physical Deterioration.

On this subject Lieutenant-Colonel O. T. **DUKE**, R.A.M.C., read a valuable paper, referring most of the instances of national deterioration to the faulty precautions taken by mothers with regard to their own health and to the vicious methods of up-bringing to which the infants were often subjected.

Mr. H. **BEALE COLLINS** (Kingston-on-Thames) read a paper entitled

Imperialism and the Doctor.

He said that a prominent politician had advised them all to think imperially. The health officer in his parochial work and the practitioner curing or alleviating disease were "doctors" who had acted imperially, whatever their thinking might have been, for however insignificant the parochial part might be it was one of the parts that went to make up the imperial whole. He alluded to the imperial importance of the decreasing birth-rate, not only in this country, but in some of the colonies, and pleaded for greater care to be taken of the nursing mother.

Dr. F. G. **BUSHNELL** (Brighton) advocated the constitution of a Ministry of Public Health; and Dr. F. J. H. **COUTTS** (Blackpool) read a paper on the Administrative Control of Whooping-cough, Measles, &c., which was briefly discussed by Dr. J. W. **MASON** (Hull).

SECTION OF CHILD STUDY AND SCHOOL HYGIENE.

Alcohol and Children.

Dr. G. **CARPENTER** (London) discussed the effect of Alcohol on Children. He said there was a popular idea that alcohol was not only not injurious but was beneficial to children in health as well as in disease but this was open to grave doubt. Alcoholism was not rare among children and played a far greater part in the production of disease than had been recognised. Alcohol expended its main effects in children on the nervous system.

Importance of Normal Respiration in Childhood.

This was the subject of a paper by Dr. P. **WATSON WILLIAMS** (Bristol) who said that the assimilation of oxygen and the elimination of carbonic acid were essential for the continued activity of the muscles and of the tissues generally. The causes of defective respiration were both extrinsic and intrinsic; the results and the means to be adopted for their correction were both physical and biological.

The Vision of School Children.

Dr. J. P. **WILLIAMS-FREEMAN** (Andover) had investigated the eyesight of 1442 school children in West Hants. The statistics showed that 64 per cent. had normal vision as against 39 per cent. in London, according to Mr. Brudenell Carter.

Dr. J. A. **MENZIES** (Dover) discussed the

Influence of Certain Forms of Defective Sight on Education and vice versâ.

He said there was evidence to show that myopia was probably never congenital, whereas hypermetropia and astigmatism were. Education was a direct exciting cause of myopia. He advocated medical supervision of schools and education of teachers to take an intelligent interest in the sight of the children.

Mr. **JOHN JACKSON** (London) read a paper on

Ambidexterity.

He emphasised the importance of manual training for developing the special senses and the mind and went so far as to say that one-handed culture neglected one brain lobe which thus became more or less atrophied and positive mental depreciation consequently ensued.

Dr. F. J. **POYNTON** (London) discussed the

Influence of School Life on Rheumatic Children.

Children who were of rheumatic stock or who had suffered from an attack of rheumatic fever at some previous date were very frequently highly emotional and nervous. Such children were liable to get quite out of hand at home and for them the discipline of a well-conducted school was often most beneficial and brought about a distinct improvement in their general health. Where, however, active rheumatism developed school life was injurious to them. At first sight it might seem very unlikely that a child suffering from rheumatic fever could attend school, yet so insidious was the disease that among poor children this occurred repeatedly. One manifestation—viz., chorea—was nearly always rheumatic, but its importance, especially among the public, was not recognised as it should be. In three and a half years while attending the hospital twice a week he had taken notes of 225 cases of rheumatic fever in children under 12 years of age, 126 of whom had suffered from chorea. School work of all kind was injurious to the condition of chorea in the active phases.

Mr. J. **WARRINGTON HAWARD** (London) described in a sympathetic paper

The Aims and Method of the Invalid Children's Aid Association.

Many cases of disease could be treated perfectly well at home if only they could obtain a small amount of nursing help. In diseases of a chronic character the amount of medical supervision required was often small; a visit to the medical man once in two or three months would in many instances suffice if the medical instructions were properly carried out in the intervals and it was for these cases that the association was so valuable. The method of the association was described.

Dr. **LEONARD G. GUTHRIE** (London) read a paper on Mental Overstrain in Childhood and Dr. **FLETCHER BEACH** (London) discussed the Diagnosis and Treatment of Feeble-minded Children.

LADIES' SECTION.

The State Registration of Nurses

was discussed in three papers.

Mrs. **BEDFORD FENWICK** (London) gave details of what had been done in other countries in this direction and suggested the formation by Act of Parliament of a General Nursing Council and the institution of measures providing for the efficient education of nurses and granting them the legal status which was their due.

Miss **PLUM** (matron, Victoria Hospital, Folkestone) gave as her opinion that the registration of nurses by Act of Parliament was the only means by which a general standard of education and a definite system of professional control could be obtained; the standard should be a high one in all hospitals. By giving a recognised status to competent nurses a good stamp of women would be attracted to the nursing ranks.

Miss **ALICE BARLING** (Borough Sanatorium, Folkestone) discussed State registration as it affected the private and the public nurse. She described instances of how at present anyone with the smallest knowledge might style herself a nurse and considered that State registration would be of immense advantage both to the public and to the medical practitioner

Dr R S MARSDEN (Birkenhead) said they must all agree that the case for the registration of nurses had been made out but they could n
nurse any more than
a doctor The untrai
their living in the same way It was not physiology that the nurse wanted it was common sense

Mrs SCHARLIEB M D (London), read an instructive paper on

Laws of Health for Girls during the years of Adolescence, at Home and at School

She discussed her theme under the headings of (*a*) pure air, (*b*) adequate warmth, (*c*) suitable food, (*d*) duly regulated exercise and rest, (*e*) personal care and cleanliness, and (*f*) environment

SECTION OF BACTERIOLOGY

Milk-supply

The papers which came under discussion at the meeting of this section were the Collection and Transit of Milk from the Bacteriological Point of View—(*a*) the Methods Adopted by Railway Companies, by Dr T D LISTER (London) (*b*) Bacterial Contents of Milk at the Points of Origin and Distribution by Dr J W H EYRE (London) showing the great increase in bacterial contamination when milk reached the consumer, (*c*) Bacteriological Technique by Mr G L EASTES (London) dealing with the methods of examining milk, and (*d*) Veterinary Control of Dairy Herds by Mr S VILLAR F R C V S (Harrow) who pointed out that the necessity for veterinary supervision of dairy herds was not sufficiently recognised The most important point in securing the purity and good quality of milk was that it should be produced by healthy and clean cows which were kept in healthy and clean surroundings It was a common thing for milking cows to be kept in a filthy condition in most insanitary surroundings To the veterinary surgeon should fall the duty of insuring that the cows were properly and sufficiently fed, that their water supply was pure their sheds kept clean, and many other details

At the conclusion of the morning sitting the following motion was adopted —

That this section hereby forwards to the council of the Institute the following resolution—viz That this section being of opinion that
nterest, for the purposes of
sumer hereby requests the
alth to consider the whole
decision

Mr W HUNTING, F R C V S (London) read a paper on

The State Control of Measures for Stamping Out Glanders,

in which he advocated the compulsory notification of all cases compulsory slaughter of diseased animals, use of mallein to detect latent disease and cleaning and disinfection of stables and Mr MCPHAIL, M R C V S (Edinburgh) urged the necessity for municipal veterinary inspection

SECTION OF ENGINEERING AND BUILDING CONSTRUCTION

Mr FRANCIS GOODRICH (London) discussed the

Disposal of the Waste of Public Institutions and Works

in which he described various forms of destructors and the same subject was also dealt with by Mr I L WATSON, A M I C E (Leeds)

Mr WILLIAM MAXWELL A M I C E (Tunbridge Wells), read a paper on

The Conservation of Subterranean Water supplies

He concluded that having regard to the large and increasing population in this country entirely dependent upon subterranean water supplies the question of conserving and augmenting this source of supply was one of growing importance and was destined to play an important part in the sanitary and water engineering works of the future

SUB SECTION OF PHYSICAL TRAINING OF THE FORCES.

Surgeon General G J H EVATT, C B, read a paper entitled "Suggestions for the Improved Organisation of the Medical Services of the Volunteer Forces, and Brigade Surgeon Lieutenant Colonel J L TURTON A M R, dealt with a similar topic as affecting the Army Medical Reserve while Brigade Surgeon Lieutenant-Colonel W HILL CLIMO discussed Military Service and National Health

ANNUAL GENERAL MEETING

The annual general meeting was held on July 26th, when votes of thanks were passed to the President, the Earl of Radnor, to the Mayor of Folkestone and the local committee to the Dean of Canterbury and other ministers, and to the presidents, vice presidents, and secretaries of sections

Dr W R SMITH was re elected President of the Institute and the nomination of officers and council was accepted

THE OPENING OF THE "POLICLINICO" AT ROME

(FROM OUR ROME CORRESPONDENT)

ABOUT 30 years ago when the proposal was made by Guido Baccelli that the various clinics of Rome should be united under one roof, these institutions were scattered over the city at points so distant from one another that little or no coöperation was possible between them and a vast deal of expense was incurred in the maintenance of a number of separate and independent establishments which could ill be spared from the scanty funds available Not only so, but the buildings, mostly old monasteries and churches, in which they were housed were out of repair and totally unfitted from their construction and surroundings to the purposes of a hospital They were overcrowded and ill ventilated, and on account of want of space and suitable premises it was impossible to organise their service in an efficient and satisfactory manner Whilst this condition of things was detrimental to the interests of patients to a degree which cannot be estimated, but was certainly deplorable the interests of the medical profession suffered to a corresponding degree Much time was necessarily wasted by students in passing from one section of their clinical studies to another and much valuable material for study was lost owing to the impossibility of making use of it For the surgeons and physicians who had to do their work under such conditions the difficulties were enormous and for the former especially, well nigh insurmountable It is true that the results of operative work by such men as Durante, Postempski Mazzoni and Bastianelli in the Roman wards will compare favourably with that accomplished elsewhere under all the advantages which modern science supplies But these results have been secured in the face of difficulties which would make most surgeons despair and the removal of these difficulties will undoubtedly give a great impetus to Roman surgery

The idea put forward by Baccelli and elaborated by Durante was caught up with enthusiasm by the nation and
50 000,000 lire (£2 000 000) was
to the municipality of Rome for
the amount was provided for the
express purpose of carrying out this scheme In 1881 the principal clinicians of Italy met in Rome to place the project on a scientific basis and architects were invited to compete for the construction of the new hospital The successful competitor was Podesti and after many delays, due chiefly to the difficulty of choosing a suitable site, the work was at length begun in 1888 For a time the buildings were pushed on with alacrity and already in 1894, when the great International Congress of Medicine, which was attended by 9000 medical men, met in Rome all the members were impressed by the vastness of the structure The work continued to progress, though more slowly until in 1900 it was practically complete Unfortunately, as pointed out by Professor Bossi a few weeks ago in the Chamber of Deputies, the handing over of the management of the Policlinico in that year to the Board of Administration of the Roman Hospitals led to much delay and to some mistakes One serious error committed under its direction was to place 100 beds in each pavilion in two wards, one over the other and communicating in such a way that the vitiated air from the lower ward flowed into that above An attempt was also made to omit the arrangements for central heating on the plea that in Rome these were unnecessary and that heating the wards by simple braziers would be sufficient Such changes and disputes, together with want of the funds necessary to prosecute with dispatch the completion of the corridors

connecting the pavilions and of the internal fittings and furnishings, led to delays that seemed interminable and to injuries to the building itself inevitable in an edifice kept closed and uninhabited. Large sums have been required to make good the damage so caused, adding considerably to the cost, already enormous, of the structure itself, a cost which has nearly approached a total of three-quarters of a million pounds sterling.

A few facts and figures cited by Professor Bossi in the speech already referred to serve to show the pressing need which existed for the speedy opening of the Policlinico. In the first place, it is impossible to complete the systematising of the Tiber until the part of the Hospital of Santo Spirito now occupied by Professor Baccelli's clinic has been pulled down and the way opened up for the building of the new bridge over the river, the Ponte Vittorio Emanuele, by which it is proposed to connect the "Città Leonina" with the "Città Urbana." Secondly, the present condition of the various clinics as regards space, buildings, and such-like requirements is quite inadequate to modern needs in respect of hygiene, scientific progress, and teaching facilities. For example, the surgical clinic has officially but 27 beds for 200 students and Professor Durante who directs it has been obliged to convert part of his wards into a *casa di salute* in order that, by taking paying patients, he might be able to increase the number of his beds from 27 to 60. The obstetric clinic with 200 students is limited to 20 beds for obstetric and ten beds for gynæcological cases. Again, as already indicated, the distance between some of these clinics is so great that it is not possible for the most zealous students to frequent them all. For example, the medical and pediatric clinics at Santo Spirito, the obstetric clinic at San Giovanni, the surgical clinic in the Via Garibaldi, and the dermosyphilitic clinic at San Gallicano are almost as widely separated as they could possibly be. Finally, in respect of sanitary conditions it need only be remembered that the hospital accommodation of Rome in 1870, when the population numbered 180,000 inhabitants, was the same as it was at the beginning of the present month with a population now numbering 500,000. The consequences may easily be imagined. The hospital wards contain twice or even thrice as many patients as they ought to accommodate. To cite only one or two instances, the ward of San Carlo at Santo Spirito, adapted for 100 beds, holds at times as many as 228, and that of Santa Maria at the same hospital contains 140 in place of the normal 85. At San Giovanni the ward Pucinotti contains about 100 instead of 50 and the ward Mazzoni 110 instead of 64. At San Giacomo, in the Corso, it was necessary to appropriate as wards the rooms occupied by the nurses and attendants who have been obliged to live outside, thus greatly weakening the service of the hospital. As a result of this overcrowding tuberculous patients are unavoidably placed side by side with those suffering from other diseases, and it is a fact that as many as ten of these cases may be found in each ward of Santo Spirito, constituting so many permanent foci of infection. The state of things in the maternity hospitals is more deplorable. In these and in San Giovanni there are altogether 75 beds available for the annual 7500 parturient poor of Rome. It frequently happens that one of these unfortunates, on the eve of being confined, has to go the round of all the institutions before finding a bed, and, still worse, on the third, fourth, or fifth day of the puerperium has to be sent out to make room for some other.

At least until a few days ago such has continued to be the condition of the Roman hospitals. But, happily, the long looked for opening of the Policlinico is at last an accomplished fact, for on August 2nd the arrangements for the reception of patients were complete and on the 5th there had been admitted over 500 patients, nearly all of whom were conveyed from San Spirito, San Giacomo, and San Giovanni. At present the patients are placed in the ten central pavilions and none of the surrounding clinics are occupied, but it is hoped that funds will still be found to equip the latter or at least the two general clinics of medicine and surgery. It will thus be seen that although now open, and although the pressure on the other three great hospitals is thereby relieved, yet the Policlinico still falls short of realising the original conception of Baccelli whose idea was to build a model hospital of at least 1200 beds surrounded by all the clinics. The sinews of war were lacking and the design of the architect as it stood in 1883 could not be executed in its entirety; indeed, it is said that at one period—in 1898—the financial outlook was so gloomy that it seemed as if the whole enterprise must collapse and there was even some talk of converting the buildings into military barracks. Happily it was possible to introduce modifications which curtailed the expense and so saved the institution from shipwreck, but these necessarily sacrificed a part of the original plans and so restricted the hospital to its present less ambitious proportions. Even in its actual state it covers 160,000 square metres and consists of 26 large buildings and many smaller ones. There are ten pavilions, each capable of receiving 84 patients, a special wing for infectious cases, and a great central building for administrative purposes; also buildings for clinics of medicine, surgery, obstetrics, gynæcology, dermo-syphilopathy, ophthalmology, pediatry, as well as of oto-rhino-laryngology, of special medical and surgical pathology, and of neuropathology. The following professors, each with two assistants, have been appointed "primarii" to the pavilions—viz., on the surgical side R. Bastianelli, T. Ferretti, and R. Alessandri to Nos. 1, 2, and 3 respectively; and on the medical side T. Ferruccio, A. Zeri, V. Ascoli, U. Archangeli, E. Rossoni, G. Bastianelli, V. Pensuti, and T. Gualdi to the others respectively.

The opening of the Policlinico is regarded in Italy as of not merely local but of national importance, since its construction has been in great part a national undertaking and one in which the greatest pride is justly felt by all Italians who desire to see their country take its merited place in the foremost rank of science and civilisation. And it will be everywhere recognised that in carrying it through successfully Italy has done noble service to mankind in the face of the greatest difficulties and has erected a monument to her own honour which will bear lasting testimony to her charity and humanity.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Lord Chief Justice on "the Conscientious Objector."

IN the course of his remarks to the grand jury on July 28th at the Birmingham Assizes the Lord Chief Justice made some observations concerning the Vaccination Act with a view to obtaining uniformity of administration on the part of the magistrates. He wished, he said, to take the opportunity of saying a few words to them and through them to the general body of magistrates who had to discharge duties in regard to the working of this Act. He mentioned the matter on account of the very considerable number of representations which had been made to the Home Office as to the difference prevailing amongst magistrates in the administration of the Act of 1898. They were aware of the general provisions of the Act and the extremely salutary provision which had worked so well providing for vaccination at the houses of the children and thus avoiding the delay and difficulty which often arose from the parents having to take their children to be vaccinated. It certainly was a matter of great congratulation to those of them who had studied the question of the spread of the disease of small-pox to know of the improved supervision under which vaccination was now carried on, and that the salutary effects had been very marked since the Act was passed. They further knew that the legislature, in its wisdom, had thought fit to enact that there should be power to obtain, within a certain period, a certificate of exemption from vaccination on the ground that the applicant conscientiously believed that vaccination would be prejudicial to the health of his child. It was in regard to that provision that this difference of practice prevailed. Some magistrates appeared to think that they ought to be satisfied that vaccination would be harmful to the child, others seemed to think that they were entitled to have medical evidence before them that such vaccination would be prejudicial. He wished to point out that this was not the question which magistrates had to decide and it was from this point of view that he was desirous of assisting the authorities to secure uniform administration of the law. The section, as he read it, laid down two conditions, one that the person who applied "conscientiously believed," and the other that "he believed that vaccination would be prejudicial to the health of the child.' The only question the magistrates had to entertain was: Did the applicant conscientiously believe that vaccination would be prejudicial to the health of the child? With regard to the conscientious belief, of course, there were many occasions upon which there could be no doubt about it, but it was not sufficient that a man believed generally that vaccination was an improper thing or that he had been led to form that belief without considering the particular case of the child in point It must be an honest conscientious belief on the part of the applicant that vaccination would be prejudicial to the child in question It was no good to have a sort of general idea that vaccination was not good Applicants must not hold a general objection to it either on the ground of interference with the rights of the subject or on the point of parental control It must be the conscientious belief that vaccination would be prejudicial to the health of the child He trusted that by these remarks he might do something to secure a more uniform administration of the law upon the lines which he believed the statute indicated

Notification of Consumption

At the last meeting of the City Council Alderman Cook, chairman of the public health committee, brought up a recommendation from that committee that a system of voluntary notification of tuberculosis of the lung be approved and that the committee be authorised to take the necessary steps to put the same into effect He said that many years ago the treatment of consumption was taken very little notice of It was regarded as an incurable disease and he could remember the time when trade societies hesitated to admit men as members in whose family there was consumption But during the last 50 years a great deal of attention had been given to the subject By means of improved sanitation, better housing, better food, and better general regulations respecting health the ravages of consumption had been reduced by 50 per cent But a great deal remained to be done What the committee desired was to know where the cases were in order that means might be taken, if necessary, to secure the isolation of the sufferers and also to assist in preventing, as far as possible, the spreading of the disease In Birmingham there was an average annual death rate from tuberculosis of nearly 1100 and that showed the importance of the subject because, after all, small pox, scarlet fever, and the other infectious diseases did not cause anything like the number of deaths that consumption did Last quarter, of all the deaths in Birmingham one in every 12 was due to phthisis Therefore, if the committee could only do something to reduce the mortality they would accomplish a great work The notification would be regarded as absolutely confidential and would not be allowed in any way to prejudice the patient The committee would prefer compulsory notification but they thought the time had hardly arrived for that The experience of other towns was that by voluntary notification about 50 per cent of the whole of the cases were notified The cost of voluntary notification would be about £300 per annum and he thought the money would be well spent In the course of the discussion Councillor Middleton, as an official of a friendly society testified to the growth of consumption and expressed the opinion that voluntary notification would do much to help the committee in putting down the disease In his opinion there was no reason why the committee should not endeavour to stamp out the disease by the provision of sanatoriums without pauperising the patients as might be the case if the work were undertaken by the board of guardians It was quite as important that the disease should be stamped out as it was that they should get rid of scarlet fever and small pox In reply to various questions which had been raised in the course of the debate Alderman Cook stated that the first step would be to see how far [illegible]

[illegible] people to carry out suggestions which in the ordinary way would not occur to them They were proposing to circularise every medical man in the city that they would be paid the same rate for notification as in the case of other diseases—namely, 2*s* 6*d* per case The committee expected to receive through medical men information of about 50 per cent of the cases He added that he thought the voluntary notification would in a reasonable time lead to compulsory notification It was doubtful whether the climate of Birmingham was suitable for a sanatorium but something might be done in the way of making provision for the very poor He thought they could accomplish more by preventing contact than by climatic improvement They were completing the hospital in Yardley road and he was hopeful that in due course the health committee would have some recommendation to make which would meet with the approval of the Council The motion for voluntary notification was carried

'Homes, Limited

It will be remembered that, as detailed by me in a former letter, this company was started with the intention of providing cheap and sanitary homes for the poor in the centre of the city The company chose a site in the very centre of the city, erected admirable buildings, and offered 60 dwellings at rents varying from 3*s* to 4*s* 3*d* and 5*s* per week The remarkable fact that has appeared after the first year of this experiment has been that the company, instead of having been overwhelmed with applications has actually found it difficult to secure tenants This is a pungent criticism on the contentions of some that the city council was to blame for not launching out into a huge scheme for the erection of such dwellings

August 10th

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

The Royal Infirmary Trustees

A SPECIAL general meeting of the trustees of the Manchester Royal Infirmary was held on July 27th to consider, and if thought advisable to approve, the following motion —

> That the plans for the new infirmary on the Stanley grove site with the estimate of cost being submitted to the trustees the board of management be authorised to proceed with the building of the new infirmary at Stanley grove

The chairman Mr W Cobbett, moved its adoption He said that the building of the new infirmary would occupy three years The plans and estimates were before the meeting They had been approved by the board of management and the medical board and it was for the trustees to sanction them or otherwise The estimate for providing accommodation for 589 beds was £322,193, with the addition of £16 109 for extras making a total of £338 302 With architects commission, payments to clerk of the works and others the cost of furnishing, &c, the total estimate came to £430 475 He then touched on a question exciting much interest, that of a central receiving house There does not seem any urgency as to this matter just now, but many are anxious to have the question settled The board says it will consider it and when it is in a position to do so will recommend one thing or the other but it must be decided ultimately by the trustees themselves One of the matters to be considered is the provision of ambulances A subcommittee of the board was appointed to meet the watch committee of the corporation which met the subcommittee sympathetically and said practically that if the board would provide buildings at the new infirmary it would make it one of its principal stations and 'run the ambulance' at the expense of the corporation There has not been time yet to complete the negotiations An amendment to the motion was moved approving of the plans except for the out-patient department Those for this department are to be held in abeyance till the question of an emergency hospital near Piccadilly be decided In the event of such provision being made the out patient department would not require to be as extensive as shown on the present plan After a good deal of discussion the motion with the following addition was suggested by the chairman —

> This resolution is without prejudice to the question of the provision of a central receiving house and out patients department which the board undertake to consider and make a recommendation upon to the trustees at the earliest possible moment

Many think that with the constantly increasing facilities for locomotion and the provision of a good ambulance service there is no longer any need for a central hospital, with its out patient department and separate requirements as to administration Others think it would be a 'terrible mistake not to have a central receiving hospital No doubt the *pros* and *cons* of the question will be well threshed out One of the trustees urged careful consideration of the great cost to which they were committing themselves As he said, the estimated cost is between £700 and £800 per bed and the cost of maintenance would be on a higher scale than at the present infirmary The cost per bed does seem very high but this gentleman did not propose any plan for its reduction.

Hospital Amalgamation.

Negotiations have been proceeding for some time between the boards of management of the St. Mary's and the Southern Hospital and the authorities of the Victoria University that have resulted in an arrangement for the amalgamation of the two hospitals. This is subject to the approval of the subscribers, which, however, will probably be obtained. The new hospital in Gloucester-street will be devoted to maternity cases and will provide about 100 beds and a training institution in midwifery for students and nurses. An out-patients' department for women and children will also be retained there. The Southern Hospital will be built on a site facing Oxford-road, opposite Whitworth Park, and will be used for the treatment of the diseases of women and children. When the scheme is completed there will be 225 beds devoted to midwifery and the diseases of women and children. "There will also be a school for the education of medical students, midwives, and midwifery nurses," an arrangement which reads curiously to those whose ideas have not progressed with sufficient rapidity. The danger of overlapping will certainly be removed. The title is to be "The St. Mary's Hospitals," but probably the old names will continue to be used for the sake of distinction.

Reservoirs at Audenshaw.

At the meeting of the Manchester city council on August 3rd Alderman Sir John Harwood made a somewhat disquieting statement as to the Audenshaw reservoirs and works. They are near Manchester and serve as the distributing centre for the water supplied by the Woodhead chain of reservoirs. He said that the waterworks committee had been anxious about them for a considerable time and had been watching them closely both day and night for more than two years. There are coal-mine workings in the neighbourhood which have caused sinking of the ground and "have made it necessary to reduce the holding capacity of the reservoirs in that township below top-water level to an extent equal to the loss of 330,000,000 of gallons." The whole district—houses and a chapel—has been damaged and sunk between two and three feet and the movement is steadily going on. When the corporation bought the land it was not aware that it was intended to get coal under it "and to buy out the coal would be a very expensive matter indeed." Sir John Harwood says that the corporation is not in any way to blame, but it is, at any rate, unfortunate that its advisers did not make such inquiries as would have enabled the corporation to protect itself against such a contingency as that now threatening. Sir John Harwood says, moreover, that in law they are entitled to support for their lands, but it would seem a difficult task to prop up a reservoir. Whether the subsidence will go much further depends, of course, on the character and extent of the working of the coal mine, as to which no information was given.

Death from Anthrax.

An inquest was held at Altrincham on August 6th concerning the death of a hawker. On August 2nd he took a load of bones to Manchester and afterwards complained of pain in his arm. He was taken to the Altrincham Hospital where he died. The medical evidence attributed the death to anthrax, "which might have been contracted on the Tuesday or have been in the man's system a fortnight." No details of the case are reported. Outbreaks of anthrax have occurred so frequently of late in Cheshire as to cause much anxiety. One of the districts recently visited is Malpas, where 15 pigs were affected, most of which died and were cremated.

August 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Payment of Poor-law Medical Substitutes.

AT a meeting of the Mountmellick guardians held on August 6th the application for leave of absence from Mr. E. F. Hogan was considered. Mr. D. Edgar Flinn, medical inspector of the Local Government Board, attended, and at his request a letter dated July 12th was read from the Local Government Board suggesting that the guardians should grant not only the full four weeks' leave of absence to their medical officer but should also pay his substitute for the entire period. Mr. Flinn mentioned that a special Act of Parliament had been passed securing recoupment to boards of guardians of the fees of medical officers' substitutes. The Chief Secretary had stated that if any cases of hardship were brought to his notice he would make the leave compulsory. Now it is years since a former Chief Secretary promised that a month's leave would soon be rendered legally compulsory in all cases. Observe the result in this particular case: Mr. Hogan was granted two weeks' leave, his substitute to be paid at the rate of three guineas a week only.

The late Dr. W. A. McKeown.

At a meeting of the friends of the late Dr. McKeown held in Belfast on August 2nd it was unanimously decided that "a suitable memorial should be raised to perpetuate his memory." A committee was appointed to further the object. The form which the memorial is to take has not yet been decided upon.

The Proposed Sanatorium for Consumptive Patients.

At a meeting of the Belfast corporation held on August 2nd it was decided to erect a municipal sanatorium for consumptives through which annually 300 to 400 patients might go. It is proposed to take early cases from the guardians, who will pay half the maintenance, and paying patients will also be received. It is said that 1100 people die from pulmonary tuberculosis each year in Belfast, and in the past four weeks 79 have succumbed to it, so an institution for this preventable disease is much needed in the city.

Rainfall in July in Ulster.

Rain fell in Ulster to the extent of 3·75 inches (which is rather under the average—3·92) on 24 days in July. The total rainfall this year is now 20·78 inches, which is slightly under the average and distinctly less than in 1903. The old tradition in regard to July 15th has not held true, as St. Swithin's day was an extremely wet one.

Royal Victoria Hospital, Belfast.

Mrs. Pirrie has just presented 17 beautiful iron enamelled medicine cabinets to the hospital for each of the wards, which makes the furnishing very complete, and indicates the continued interest taken in this institution by one who has been such a generous benefactor.

Ulster Eye, Ear, and Throat Hospital.

Dr. W. M. Killen, who for the past 14 years has been assistant surgeon, has been promoted to fill the post of surgeon in place of the late Dr. McKeown. Dr. R. Allen has been selected as assistant surgeon.

Outbreak of Small-pox in Armagh.

A patient from near Middletown, county Armagh, who was admitted to the union hospital in the city of Armagh with small-pox died there on August 3rd, and five new cases have since been admitted and nine "contacts" have been isolated. A very large number of people are being vaccinated, although it would appear that the Local Government Board has not been able to supply an adequate amount of calf lymph, owing to which considerable disappointment prevailed among those who wished to be revaccinated. A case of small-pox has occurred in the person of a police-constable in the barracks, Barleek, in the Newry union. This case is believed to have been imported from the town of Armagh. The disease has made its appearance also in Dublin.

The Belfast Ambulance System.

The work in connexion with the ambulance branch of the Belfast fire brigade has been very arduous during the year ended June 30th last, 2393 calls having been received, occupying 1343 hours 41 minutes, and showing an average of 33⅗ minutes per journey from the receipt of the call until the carriage returned to its station. The distance traversed was 8249½ miles, or an average of three and a half miles per single journey.

August 9th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Action of Sulphurous Waters upon a Mercurial Course.

IT has been demonstrated in varying circumstances that the administration of sulphurous waters to patients undergoing a mercurial course of treatment will prevent the phenomena of mercurialism. At the meeting of the Medico-Chirurgical Society, which was held on July 11th, M. Desmoulière cited two interesting observations which go to support the above statement. From his researches he had ascertained that in addition to the known effect of sulphurous waters upon the excretions, both cutaneous and urinary, it was necessary, in order to explain their effect upon a course of mercurial treatment, to take into consideration the following facts. The absorption of mercurial salts by the organism is under certain conditions very slow, as, for instance, when they are given by the mouth in the form of the bichloride or the proto-iodide, or when they are given by injections, especially when insoluble salts are used. These mercurial salts form albuminates which remain unabsorbed and cannot act until they are rendered soluble. Sulphurous waters, however, contain compounds which are capable of dissolving these albuminates with much greater facility than chloride of sodium which is the chief means by which the organism is capal [illegible] therefore, that th [illegible] during a mercurial [illegible] mercury as it is ad [illegible]

The Effect of Diuresis on Albuminuria.

At the meeting of the Society of Biology which was held on July 16th M. Javal stated that he had observed that in the case of nephritic patients, the hydration of whose tissues varied very little, the ingestion of an excess of water simply diluted the albumin. Therefore if the amount of albumin was estimated as so much per litre of urine passed it appeared less than before, but in reality the total amount remained the same. In cases of polyuria, if the increase in the volume of urine passed was due to dehydration of the organism, the effect on the albuminuria was by no means the same as when the polyuria was due to the ingestion of a large quantity of water. Therefore, in studying the amount of albumin passed by a patient suffering from nephritis it was important to take into account the variations in the total quantity of urine passed and the causes of these variations, for it will easily be seen that the total amount of albumin passed during 24 hours gives figures much more trustworthy than a mere estimation expressed in terms of so much per litre of urine passed.

The Treatment of Varices and of Phlebitis by Movement.

At the meeting of the Academy of Medicine which was held on July 26th M. Lucas-Championnière read a paper upon some researches of M. Marchais concerning the Treatment of Varices by Exercise. This treatment is a natural corollary to the bold surgical treatment of the veins which followed upon the introduction of the antiseptic system. Veins can now be tied, cut, excised, or treated just in the same way as any other tissue provided that sepsis is avoided. Recently even inflamed veins have been removed. Phlebitis and embolism are not necessary consequences of traumatism or movement and since 1878 *M. Marchais has given up keeping his female patients* who were suffering from phlebitis at rest. As for embolism, those cases which occur very uncommonly and have been observed in patients suffering from fracture have had nothing to do with movement, for those which M. Marchais has been able to collect, whether in his own practice or in that of other surgeons, have occurred when the fracture had been immobilised and kept absolutely at rest. He therefore considers that the complications of phlebitis are rather the consequence of treatment by rest than of the phlebitis itself. In cases of varix M. Marchais forbids his patients to stand still but treats them by gentle massage and walking. Elastic stockings are banned and as a preliminary to the walking he uses massage for from 15 to 20 days previously. Then he makes his patients walk quickly—i.e., at least 100 steps per minute. Only a short distance is walked at the beginning, but eventually the patient walks for an hour or even two hours. Swedish exercises are also useful as well as the use of the tricycle or bicycle.

Experimental Reproduction of the "Mal de Bassine."

"Mal de bassine" *is a trade dermatosis* which under certain conditions attacks the hands of silk-winders who are employed upon cocoons reputed to be "sick." M. Heim and M. Pautrier have made a special study of this disease and communicated a paper thereon to the Society of Biology at the meeting held on July 23rd. Some observers have attributed the disease to the product of putrefaction from the chrysalis as it macerates in the warm water of the "bassine," others to some vesicating product of the silkworm which is taken up by the silk. M. Heim and M. Pautrier took cocoons from lots which had apparently given rise to this dermatosis and rubbed the chrysalides up with an oily substance so as to form an ointment. This ointment applied to the skin gave rise to a dermatosis closely resembling other artificial dermatites. The skin became red, œdematous, and sometimes small vesicles appeared. It is evident, then, that the chrysalis of the mulberry silkworm contains a vesicating principle which with the aid of the macerated condition brought about by the warm water will reproduce when applied to the skin a dermatosis exactly like that called "mal de bassine."

The Action of Radium upon some Nervous Maladies.

M. Raymond and M Zimmer communicated to the Academy of Medicine on July 26th the results of the application of a tube of radium containing five cubic centimetres to various patients suffering from nervous affections. The tube was kindly lent by M. Curie. In hysterical cases the results were *nil* and the same was the case in musculo-spiral paralysis and acute facial neuralgia. Very remarkable results, however, were obtained as regards the painful phenomena of tabes Peripheral pains were rapidly and completely relieved and in several grave instances of gastric crisis great relief was obtained. These results induced the observers to try the effects of x rays and they consider that they met with great encouragement. They intend to communicate these results at some future meeting of the Academy.

August 9th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Study of Medicine in Germany.

THE central committee of the German Practitioners' Association has just issued a warning to those who may be thinking of entering the medical profession. The committee states that so long ago as 1887 it had addressed school authorities and the daily press to the same effect and that at the time the condition of the medical profession was described as "difficult, perhaps unfavourable," and its prospects as sad. This prediction, now says the committee, has proved true, the standard of life of the profession being considerably lower at present than at any previous time. Three causes are alleged for this condition—overcrowding of the profession, the abolition of the anti-quackery laws, and the legislation on the workmen's insurance. The number of medical men has doubled since 1876 and they reside in any place where there is a chance for them to gain a modest livelihood even under the greatest difficulties. The abolition of the anti-quackery laws has had the effect of increasing the number of unqualified people practising medicine. Disreputable persons, sometimes former criminals, get an extensive *clientèle* by unscrupulous advertisements and arrange public meetings at which qualified medical men are attacked and insulted. It is remarkable that even cultivated laymen are inclined to prefer the advice of unqualified persons, so that in some places in Germany their number exceeds that of the qualified practitioners. Concerning the influence of the workmen's insurance laws the committee alludes to the insufficient fees paid by the clubs, to the dependent position of the club medical officers, and to the necessity of canvassing for employment at clubs. Since nine millions of people—i.e., more than one-sixth of the population—belong to sick clubs, their influence is very great. The competition for club appointments has indeed been very prejudicial to professional etiquette and has led to disagreeable controversies between medical men, especially in the smaller towns. Although the opinion of the committee is well founded and clearly expressed it is very unlikely that it will have any influence on the forthcoming candidates for the medical career.

Medical Degrees.

During the winter semester 611 medical men took the degree of M.D. at the German universities. Of these 101 graduated at Leipsic and 26 only at Berlin, though the latter university has the greatest number of medical students. The cause is that the degree is little more than a formality, have been met, on self-supporting lines. It is hoped to raise £1000 by public subscription to enable a beginning to be made. Only women and girls will be taken at first. Patients are to be of three classes—(1) paying £2 or more a week; (2) paying £1 a week; and (3) paying 7*s*. 6*d*. a week.

Friendly Societies and Lodge Surgeons.

An action was recently tried in the county court, Melbourne, arising indirectly out of the establishment of a friendly societies' institute at Brunswick. When the various societies agreed on this undertaking they gave no proper notice to their respective lodge surgeons of the termination of their agreements but simply advertised for medical officers to the institute. In this action Dr. D. E. Stewart sought to recover from the trustees of the Shamrock Lodge, United Ancient Order of Druids, for medical attendance on members of the lodge for the quarter beginning February last and £5 for breach of contract to employ him as medical officer of the lodge; also damages for failure to pay the amount due for the previous quarter in time, and failure to furnish a list of members on whom he was to attend. The defendants paid £2 2*s*. into court in satisfaction of the first claim and 1*s*. for the third claim. The judge found for the plaintiff for the amount paid into court. On the issue as to breach of contract he found for the defendants.

Obituary.

Dr. Thomas Baynton, an old resident of Sydney, died at his residence, Ashfield, on June 6th. He arrived in Australia in 1840 and 30 years ago started practice in Sydney, having previously been engaged in pastoral pursuits. He leaves a widow who has been a frequent contributor to the Sydney press and has published a series of sketches in book form.

July 4th.

Medical News.

UNIVERSITY OF LIVERPOOL.—At examinations held in the Faculty of Medicine in July the following candidates were successful:—

SECOND M.B. AND CH.B. EXAMINATION.

Anatomy and Physiolog.—J. W. Cropper and G. W. Williams.
Materia Medica and Pharmacy.—T. T. Apsimon, E R. Armstrong, A. C. Edwards, S. J. C. Holden, A. Jones, T. Martlew, W. R. Pierce, J. H. Rawlinson, A. M. M. Roberts, R. S. Taylor, and S. V. Tinsley.

FINAL M.B. AND CH.B. EXAMINATION.

Part I.—J. F. Edmiston, B. T. J. Glover, T. E. Jones, J. F. McCann, J. McClellan, S. W. McLellan, R. H. Mole, L. D. Napier, T. W. Parry, C. H. Smith, F. H. Storey, C. Yorke, and W. Yorke.
Part II.—A. E. Grisewood,* W. L. Hawksley,* P. Hick, G. J. Keane,* W. A. Kidd,* G. C. Scott,* and T. E. Walker.

* With second-class honours.

The Diploma in Public Health has been awarded to—

D. T. Parry, M.D. R.U.I.

The Diploma in Tropical Medicine has been awarded to the following:—

. M. Clayton, M.B., B.S. Durh.; Saiduzzafor Khan, M.B. Edin. P. Hehir, Major I.M.S., M.D. Brux., F.R.C S Eng.; A. R. Maclurkin M.B., Ch.B Glasg.; J. E. Nicholson, Lieutenant-Colonel R A.M.C., M.R.C.S. Eng., L.R.C.P. Lond.; and N. Phillipson, L.R.C.P. & S. Edin.

The Diploma in Veterinary Hygiene has been awarded to—

E. E. Martin, Captain A.V.D., M.R.C.V.S.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin*: Dr. Anton v. Eiselsberg, now of Vienna, has been offered the chair of Surgery in the Charité, which is being vacated by the retirement of Professor Franz König.—*Bologna*: Dr. J. C. Ferrari of Modena has been recognised as *privat-docent* of Psychiatry and Dr. Ivo Bandi as *privat-docent* of Hygiene.—*Bonn*: Dr. Binswanger having declined the chair of Mental Diseases, Dr. A. Westphal of Greifswald, a son of the late well-known Berlin professor, has been appointed. Dr. W. Reis has been recognised as *privat-docent* of Ophthalmology.—*Breslau*: Dr. Eduard Müller has been recognised as *privat-docent* of Internal Medicine.—*Freiburg*: Dr. Determann of St. Blasien has been recognised as *privat-docent* of Internal Medicine.—*Giessen*: Dr. P. Krömer has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Kieff*: Dr. Szymanovski has been appointed to succeed Professor Khodin in the chair of Ophthalmology.—*Königsberg*: Dr. A. Stieda has been recognised as *privat-docent* of Surgery and Orthopædics. Dr. Hermann Streit has been recognised as *privat-docent* of Otology and Rhinology.—*Leipsic*: Dr. Hans [illegible] of Internal Medicine, has been appoir [illegible]ofessor.—*Marburg*: Dr. Lohmann has been recognised as *privat-docent* of Physiology.—*Munich*: Dr. Arno Scheibe has been recognised as *privat-docent* of Otology and Dr. Hubert Gebele as *privat-docent* of Surgery.—*Naples*: Dr. Giuseppe D'Arrigo has been recognised as *privat-docent* of Pathological Anatomy.—*Padua*: Dr. Amilcare Bietti of Pavia has been recognised as *privat-docent* of Ophthalmology.—*Pavia*: Dr. Domenico Della Rovere of Bologna has been recognised as *privat-docent* of Pathological Anatomy.—*Rio de Janeiro*: Dr. Luiz da Costa Chaves Faria has been promoted to the chair of Dermatology in succession to the late Dr. João Pizarro Gabizo.—*St. Petersburg (Military Medical Academy)*: Dr. A. Favitski has been promoted to an Extraordinary Professorship of Therapeutics.—*Strasburg*: Dr. Heinrich Ehret, *privat-docent* of Internal Medicine, has been appointed Extraordinary Professor.—*Tomsk*: Dr. Avroroff of St. Petersburg has been appointed Extraordinary Professor of General Pathology.—*Tübingen*: Dr. P. Linser has been recognised as *privat-docent* of Dermatology.—*Vienna*: The council of medical professors has decided to divide the chair of Pharmacology now vacant by the retirement of Professor v. Vogel into two professorships—one of Pharmacology, which has been offered to Professor Hans Meyer of Marburg, and one of Pharmacognosis, which has been offered to Professor Josef Moeller of Gratz.

PHYSICAL VOICE-TRAINING SOCIETY.—On July 29th, at the Clarendon Hotel, Oxford, a breakfast was given by Miss D'Orsey, honorary secretary of the above society, to some of the members of the British Medical Association, and a short business meeting was subsequently held. Canon Ince (regius professor of Divinity and one of the vice-presidents of the society) presided, while Dr. P. Watson Williams (Clifton) acted as vice-chairman. Amongst others present were Canon R. Ottley (regius professor of pastoral theology), Dr. W. Jobson Horne (London), Dr. E. Morton (Wolverhampton), Dr. A. T. Schofield (London), Dr. and Mrs. Stark, M.D. (Oxford), Mr. J. Stewart (Bristol), Dr. Herbert Tilley (London), and Dr. J. Wallace (Weston-super-Mare). The chairman proposed the following motion:—

> That the subject of voice-training, being of such vital importance to public speakers, greater attention should be paid to it in education, especially at the public schools and universities, in accordance with the memorial on voice-training of the British Medical Association.

Dr. Williams seconded the motion and said that medical men were being constantly brought into contact with the evil effects of bad voice production. He was of opinion that the educational authorities should take steps by which the evil could be remedied.—The motion was carried.—Dr. Horne then proposed the following motion:—

> That the *Physical Voice-Training Society*, founded by the originators of the memorial on voice training issued by the British Medical Association on Nov. 18th, 1893, is deserving of further support from the medical profession in general and the laryngologists in particular.

Personally he would like to see a national system of voice training established and for that reason he had pleasure in proposing the motion. Dr. Tilley seconded and said that voice training was a question of vital national importance. Some time ago he was invited by the London School Board to give a series of lectures on voice production. At the conclusion of the lectures he was asked to make a report. He did so and he considered that it was foolish that any girl between the age of 20 and 23 who had passed a difficult examination at great expense should be given a class of from 70 to 80 scholars and expected to speak to them for hours without any instruction as to the right use of the voice. He had suggested to the London School Board that if they would only appoint a dozen capable persons who understood the subject of voice production an enormous amount of good would accrue.—The motion was carried.—Dr. Schofield proposed a vote of thanks to Canon Ince and Miss D'Orsey.—The motion was carried unanimously and Canon Ince briefly responded.—The following were elected honorary vice-presidents of the Physical Voice-Training Society—Canon Ottley, Dr. Horne, Dr. Williams, and Dr. Tilley.

PROFESSOR V. V. PODVYSOTSKI has got an extension of his term, says the *Odessa Nocosti*, as doyen of the medical faculty of the Novorossisk University.

UNIVERSITY COLLEGE, LONDON.—The Worshipful Company of Drapers has discharged the debt of the College to its bankers to the amount of £30,000. The treasurer of the College has received from Messrs. Wernher, Beit and Co. their cheque of £10,000 which had been promised to promote the incorporation of University College in the University of London. For the completion of the incorporation scheme there remain £18,000 to be raised. We understand that the new hospital will shortly be finished and will be available for clinical study for the medical session beginning in October. The session 1904–05 will begin in the Faculties of Arts and Laws and of Science on Tuesday, Oct. 4th, and in the Faculty of Medicine on Monday, Oct. 3rd. The introductory lecture will be given by Professor J. N. Collie on Oct. 3rd at 4 P.M. Professor Oliver has been reappointed to the Quain Chair of Botany and Dr. F. J. Poynton has been appointed sub-dean of the Faculty of Medicine in succession to Professor G. D. Thane (resigned) who has received from the council the following resolution —

[illegible] ord their sense of the great [illegible] rendered to the College and [illegible] ears he has held the office of [illegible]

PATENT MEDICINES IN GERMANY.—Mr. Oppenheimer, British Consul-General at Frankfort-on-Main, in his annual report remarks that a law of great moment to the chemical industry which was passed in 1903 came into operation on Jan 1st, 1904. It concerns the traffic in patent medicines (*Geheim-mittel*) It is thereby enacted that only a certain small number of patent medicines may be sold, with the medical man's orders; 95 patent medicines have been excluded from public advertisement in any form, and in their case it is unlawful to recommend such patent medicines by printing on their enlcosures testimonials, certificates, statements of successes, expert evidence, and thanks. "Undoubtedly it was only intended," Mr Oppenheimer adds, "to render the sale of such patent medicines more difficult and not to prevent it altogether, but it is generally thought that the provisions of the enactment have overshot the mark. It will cause not only very considerable losses to the pharmaceutical industry but will also affect printing and lithographic establishments, paper, cardboard, glass, and cork factories, quite apart from the loss of workmen's wages. It is thought, moreover, that the prohibition of advertisement will render more easy the sale of imitation patent medicines which can in future only be detected by chance Finally, it may act as a discouragement in future to chemical factories and experts from paying the same amount of attention to the discovery of new patent medicines which until now have been a great source of revenue to the German chemical industry at large."

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Lunacy Bill Dropped.

The Lunacy Bill which the Government introduced on the morrow of the debate initiated by SIR JOHN BATTY TUKE has now been formally abandoned so far as the present session is concerned. It is hoped that it may be possible to re introduce it next year.

Medical Officers in Sparsely Populated Districts

When several of the Scotch estimates were under discussion on August 9th the question of procuring an adequate supply of medical officers in the more remote and sparsely populated districts in the Highlands of Scotland was mentioned It was pointed out by the Lord Advocate that it is exceedingly hard to find a way out of the difficulty In these districts there is little or no private practice possible, the medical officer cannot hope to obtain a much greater remuneration than the fees attaching to any public appointment which he may hold Is it to be wondered at, he asked, that young and capable men should seek openings elsewhere?

Vaccination in Scotland.

On the same evening some references were made to the administration of the vaccination laws in Scotland It was complained that a dangerous laxity is permitted On behalf of the Scotch Local Government Board the argument was used that it does not pay to make martyrs, and that for that reason the administration is less vigorous than in England But according to the Lord Advocate the majority of the people of Scotland are convinced of the value of vaccination and revaccination and no substantial grievance exists It was also elicited that only a very small quantity of humanised lymph is now used

The Home Office Administration.

On Friday, August 5th, a general discussion took place on Home Office administration, especially in reference to factories and workshops A good deal was said about the inadvisability of employing married women Mr. BURNS declared that the presence of these women in public works is one of the causes of the physical deterioration of the race To it also is due in his opinion a considerable percentage of infantile mortality. A demand for the appointment of additional women inspectors was very favourably received by the Home Secretary, who also stated that he had recently received a suggestion which he thought worthy of consideration—namely, that in addition to the qualifications which they now possessed women inspectors should have some experience of hospital work

Juvenile Smoking

The Bill to check smoking amongst juveniles which has just been introduced in the House of Common has, of course, no chance of becoming law this year It has been introduced merely for the purpose of focussing public attention on the subject. Early next session it will be re introduced. The proposal of the Bill is that any person under 16 who is found smoking shall be liable to a penalty of 10*s* —the fine to be recoverable from the parents—and that anyone selling tobacco to a child shall be liable to a fine of 20*s* for the first *offence* and 40*s* *for* the second

Hygienic Conditions of China and Earthenware Factories

Sir CHARLES DILKE asked the Home Secretary whether his attention had been called to the statement at p. 219 of the Factories Annual Report, to the effect that many china and earthenware factories were dilapidated and in great need of hygienic improvement; and whether, seeing that recommendations for the closing of the worst

Notes, Short Comments, and Answers to Correspondents.

MEDICAL ETIQUETTE.

At a meeting of the Burslem town council on August 7th Alderman T. Edwards is reported as having asked whether the medical officer of health saw all the cases of infectious disease notified before they were sent to the hospital. The chairman of the sanitary committee, Mr. Councillor Cartlidge, replied that the medical officer did not "as medical etiquette debarred him." Alderman Edwards thereupon said that the council should disregard such "etiquette." It was understood that the matter would come before the next meeting of the sanitary committee. The chairman of the sanitary committee of Burslem, in common with the majority of the public, does not understand what is meant by "medical etiquette." It is no part of the duty of a medical officer of health to pay a personal visit to every patient who is notified to him. The Infectious Diseases Notification Act imposed no fresh duties on the medical officer of health. The duty of the medical officer of health is to inquire into the circumstances and causes of an outbreak of infectious disease and he has full responsibility for how he may best carry out such an inquiry. He has no right to enter any private premises, except with a magistrate's order, but of course an application for leave to see the patient addressed to the medical man in charge of the patient and to the latter's friends would never be refused. The general practitioner is, as a rule, perfectly ready to discuss the diagnosis of a case with the medical officer of health and no trouble has ever arisen in the matter save where the medical officer of health has been unfortunately official in his demeanour. All these points have been dealt with in our columns in a series of articles which appeared in The Lancet as far back as 1895.

MOTOR-CARS FOR MEDICAL MEN.

To the Editors of The Lancet.

Sirs,—Are motor-cars cheaper than horses for a medical man? is such an important question that I feel sure you will think the statement of manufacturers' agents worth publishing space. For years I have contracted with the Victoria Carriage Co. for broughams, having a new one each year, and I lately wrote to them asking them to quote me prices for the motor-cars for which they are agents under the same conditions—that is, that they should keep it in repair and exchange for a new one every year. Their answer is that their terms would be so expensive that it would be satisfactory neither to me nor to them and they would not even give me a quotation. I keep two horses and one motor-car but so far my motor-car has cost me more than a horse, though not a year old, and my experience goes to show that no motor-car will stand regular wear, say six hours a day, for one year, and it seems that the manufacturers know it will not. I and many others would gladly pay £100 a year to feel we had a motor-car always in a fit condition to go and no horses to worry about. Will the time ever come? I am, Sirs, yours faithfully,

Plaistow, July 30th, 1904. A. E. Kennedy.

WHO IS TO PAY?

To the Editors of The Lancet.

Sirs,—A policeman during the night comes for a medical man to go to see a man at his home with a broken leg previous to removal to the union hospital. Whose duty is it to pay the night visit fee? I have received the account (5*s.*) back from the chief constable stating that he cannot pay it. Can the district medical officer be expected to attend without being paid if the man is not in receipt of relief and the police constable comes without the ordinary request paper from the relieving officer for parish attendance? I am, Sirs, yours faithfully,

August 1st, 1904. ———

*** We shall be interested to hear why this fee was not paid.—Ed. L.

THE TREATMENT OF METATARSALGIA.

To the Editors of The Lancet.

Sirs,—I should be grateful if some of your readers could give me a few hints as to the treatment of an obstinate case of metatarsalgia. The patient is a young lady, 23 years of age, and has suffered for about two years. Previous to the symptoms she had worn high heels but since then she has worn quite sensible boots. She has no excessive amount of standing or walking to do. The pain is getting worse rather than better, coming on at times in such force as to oblige her to stop in the street. I am, Sirs, yours faithfully,

August 9th, 1904. F.R.C.S.E.

THE PROMENADE CONCERTS AT QUEEN'S HALL, LONDON.

The present season of promenade concerts opened on August 6th, when the hall was packed from floor to ceiling. There is no greater rest to the mind than to listen to good music well played and Mr. Wood, his band, and those responsible for the organisation of the concerts deserve much thanks. The recent changes in the orchestra rendered it inevitable that the various items should not be given with that precision and delicacy to which Queen's Hall audiences have been accustomed, but it is also evident that in a week or so the new band may be expected to play as well as did the old one. On the opening night it struck us that Mr. Wood allowed his brass to be rather too prominent, especially as regards the trombones. The strings showed to great advantage, markedly (together with the wood wind) in the Peer Gynt Suite and by themselves in two items by Bach The only novelty in the programme was an organ concerto by Signor Enrico Bossi, which was not particularly interesting.

THE CONSULTING-ROOM THIEF.

To the Editors of The Lancet.

Sirs,—Would you kindly warn your readers against a consulting room thief who is again at large after having been in prison for numerous thefts from medical men? The man called on me to make an appointment for a "relative who lived in the country," &c., &c. Two days later he again called, this time when he knew I should be out, and asked to be allowed to wait for me as he could not come later in the day. He took what things of value he could find and soon decided that he could not wait any longer. He passes as a German or an Austrian, is well dressed, most polite in his manner, well-read, and understands every move in the game. He is about five feet seven inches in height, fair, clean shaved, and about 21 years of age; he is well set up and can easily pass as a foreign gentleman of means. He is wanted by the police for several thefts from medical men and should be detained if possible whenever he appears.

I am, Sirs, yours faithfully,

Gloucester-terrace, W., August 9th, 1904. Arthur James.

HOLMAN TESTIMONIAL FUND.

The following additional subscriptions to the above fund have been received. Further subscriptions, which may be sent to Dr. John H. Galton, Chunam, Sylvan road, Norwood, S.E, or to Mr. W. A. Berridge, Oakfield, Redhill, Surrey, are needed and will be announced at the close of the vacation.

THE Index to Vol I of 1904 which was completed with the issue of June 25th, and the Title page to the Volume, were given in THE LANCET of July 2nd

VOLUMES AND CASES

VOLUMES for the first half of the year 1904 are now ready Bound in cloth, gilt lettered, price 18*s* carriage extra

Cases for binding the half year's numbers are also ready Cloth, gilt lettered price 2*s* , by post 2*s* 3*d*

To be obtained on application to the Manager accompanied by remittance

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices 423 Strand W C , are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c , should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions post free either from THE LANCET Offices or from Agents are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed London and Westminster Bank Westminster Branch) should be made payable to the Manager, Mr CHARLES GOOD THE LANCET Offices 423 Strand London W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates, on this or on any other ground should be resisted The Proprietors of THE LANCET have for many years paid, and continue to pay the whole of the heavy cost of postage on overweight foreign issues and Agents are authorised to collect, and do so collect from the Proprietors the cost of such extra postage

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address THE MANAGER THE LANCET OFFICES 423, STRAND LONDON ENGLAND

During the week marked copies of the following newspapers have been received —*Sunday Times Ross shire Journal Reading Mercury Times of India Aberdeen Weekly Free Press Daily Mail Westminster Gazette Burnley Express Globe Bradford Observer Wigan Examiner Glasgow Herald Lincoln Herald, Windsor and Eton Express Derbyshire Courier Manchester Weekly Chronicle People's Friend Darlington Echo Hull Times Yorkshire Observer Manchester Despatch Journal of Commerce, The Standard &c*

Communications, Letters, &c., have been received from—

A.—Mr. J. S. Allen, Sheffield; A. B., Aldershot; Messrs. D. A. Appleton and Co., Lond.; Messrs. Allen and Hanburys, Lond.; Dr. B. [illegible] Aix-la-C[illegible] Products, [illegible] Secretary of; Assistant Sergeant-at-Arms, House of Commons.

B.—Dr. W. G. Barras, Govan; Dr. E. F. Bashford, Schluchtern; Dr. Richard Bevan, Lond.; Mr. J. W. Benson, Lond.; Mr. J. H. Barker, St. Louis, U.S.A.; Major G. Bent, R.A.M.C., Warwick; British Druggists, Ltd., Lond.; Mr. S. H. Benson, Lond.; T. B. Browne, Ltd., Lond.; Birmingham General Hospital, House Governor of; Mr. C. Birchall, Liverpool; Bristol Myers Co., New York; Bootle Borough Hospital, Secretary of; Dr. J. B. Bird, Carlisle; Betterment of London Association, Hon. Secretary of; Mr. W. H. Brown, Leeds; Dr. F. G. Bushnell, Brighton; Dr J. L. Bogle, Champery; Messrs. J. Beal and Son, Brighton; Mr. Arthur E. Barker, Lond.; Sir Lauder Brunton, Lond.

C.—Mrs. Margaret Cornwall, Lond.; Mr. T. J. Croke, Hull; Messrs. T. Christy and Co., Lond.; Messrs. Cassell and Co., Lond.; Dr. K. Campbell, Ebbw Vale; Messrs. T. Colman and Co., Lond.; County Asylum, Rainhill, Clerk of; Canada, Dominion of, Department of Agriculture, Ottawa; Cambridge County Club.

D.—Messrs. Down Bros., Lond.; Dr. A. Duncan, Lond.; Devon County Asylum, Exminster, Clerk of; Duryea Co., Coventry.

E.—Mr. George Vernon Edwardes, Worsley; Mr. T. Crisp English, Lond.; Mr. W. M. Emmerson, Hebburn.

F.—Dr. A. Foxwell, Birmingham; Messrs. Fairchild Bros. and Foster, Lond.; Messrs. Ferris and Co., Bristol; Dr. Charles Fraser, Lond.

G.—Mr. A. F. Bilderbeck Gomess, Lond.; Mr. Gunn, Hythe; General Register Office, Dublin.

H.—Sir C. Holman, Lond.; Messrs. Hilton and Co., Calcutta; Messrs. Hill and Sherwin, Reading; Dr. E. H. Harrison, St. Neots; Dr. Stanley Hodgson, Lond.; Mr. H. Hanson, Blackpool; Professor R. T. Hewlett, Lond.; Mr. John T. Hislop, Wrexham; Mr. Francis Hart, Lond.

I.—Ingham Infirmary, South Shields, Secretary of.

J.—Dr. E. Lloyd Jones, Cambridge; Dr. Evan Jones, Aberdare; Mr. P. A. Lloyd Jones, Bedford.

K.—Dr. C. F. Knight, Portobello; Messrs. D. J. Keymer and Co., Lond.; Messrs. H. and T. Kirby and Co., Lond.

L.—Dr. D. Lawson, Banchory; Mr. R. L. Legate, Christchurch; *Dr. H. A. Lediard, Carlisle;* Mr. Herbert Lund, Manchester; Mr. Arnold Lawson, Lond.

M.—Mr. J. M. Munro, Edinburgh; Mr. K. Monsarrat, Liverpool; Medical Graduates' College and Polyclinic, Lond., Secretary of; *Dr. John Martin, Bolton;* Miss Moss, Falmouth; Manchester Children's Hospital, Secretary of; Dr. W. Murrell, Lond.; Dr. H. R. Mill, Lond.; Manchester Medical Agency, Secretary of; Dr. George R. Murray, Newcastle; Margate, Town Clerk of.

N.—Dr. W. G. Niall, Guildford; Noble's Isle of Man Hospital, Douglas, Secretary of; Mr. H. Needes, Lond.; Mr. J. C. Needes, Lond.

O.—Dr. Thomas Oliver, Newcastle-upon-Tyne; Oriental Fibre Tooth Brush Co., Farnham; *Oaklands* Chemical Co., New York; Rev. Francis G. Oliphant, Teston.

P.—Dr. G. Steele Perkins, Lond.; Mr. Y. J. Pentland, Edinburgh; Messrs. G. P. Putnam's Sons, Lond.; Mr. T. Prince, Lond.; Messrs. Peacock and Hadley, Lond.; Dr. H. W. Plant, Shifnal.

R.—Dr. S. C. Roy, Leicester; Mr. J. D. Ryan, Rathdrum; Royal College of Surgeons in Ireland, Dublin, Registrar of; Mr. W. S. Robinson, Moseley; Rebman, Ltd., Lond.; Royal Waterloo Hospital for Children and Women, Lond., Secretary of; Dr. Stuart Ross, Clitheroe; Dr. B. Rogers, Clifton; Dr. John Reid, Lond.; Radcliffe Infirmary, Oxford, Secretary of; Messrs. Reynolds and Branson, Leeds.

S.—Mr. Simeon Snell, Sheffield; Southport Infirmary, Secretary [illegible] Professor W. Stirling, Craigmore, Bute; Dr. F. M. Sandwith, Lond.; Scholastic, Clerical, &c., Association, Lond.; Dr. T. Schott, Bad Nauheim.

T.—Mr. W. P. Tate, Downpatrick; Teale Fire Place Co., Lond.; Messrs. J. and J. Taunton, Birmingham; Miss Alice Taylor, Lond.; Tottenham Hospital, Secretary of; Mr. H. G. Taylor-Jones, Dennington.

U.—University College, Sheffield, Secretary of; University College, Bristol, Secretary of; University of Liverpool; University College, Lond., Secretary of.

W.—Dr. E. E. Wood, Edinburgh; Mr. C. Wallace, Lond.; Mr. Clarence A. Wright, Leytonstone; Mr. W. F. A. Walker, Dinas Mawddwy; Messrs. J. Wright and Co., Bristol; Messrs. A. J. Wilson and Co., Lond.; Mr. T. Winstanley, Beverley; Wisconsin College of Physicians and Surgeons, Milwaukee, Secretary of; Messrs. W. Wood and Co., New York; War Department, Bureau of Insular Affairs, Washington; Dr. R. T. Williamson, Manchester.

X.—X. Y. Z.

Z.—Messsrs. A. and M. Zimmermann, Lond.

Letters, each with enclosure, are also acknowledged from—

A.—Apollinaris Co., Lond.; A. L.; A. A. B.; A. M. R. S.; A. T. G.

B.—Mr. Haydn Brown, Eversley; Dr. J. Brown, Addlestone; Dr. J. H. Brown, Sheffield; Bethel Hospital, Norwich, Clerk of; Mr. L. C. S. Broughton, Birmingham; Brecon and Radnor [illegible] rk of; [illegible] cretary [illegible] F. E. Bissell, Northwich; Birmingham Hospital, House Governor of; Messrs. Bullock and Co., Lond.; Messrs. Burroughs, Wellcome, and Co., Lond.

C.—Mr. G. M. Cabrera, Lond.; Mr. J. Black Cameron, Lond.; Miss S. Campbell, Ajmere, India; Dr. W. Craik, Goldthorpe; The Coppice, Nottingham, C. D.; C. W. R.

D.—Dr. J. Davidson, Liverpool; Mr. G. Drury, Newcastle-on-Tyne; Mrs. Darker, Malvern; Doctor, Lond.; Mr. A. B. Duprey, St. Lucia; Dr. D. Lawson, Banchory.

E.—Dr. G. H. Edington, Glasgow; Mr. M. G. Edis, Creetown; E. J. P.; E. W. I.; E. H. H.; Mr. F. G. Ernst, Lond.; Dr. E. Elsmere, Barton-on-Humber; Messrs. Elliott, Son, and Boyton, Lond.; E. C. W.

F.—Mr. H. M. G. Forbes, Cuminestown; S. Fisher, Ltd., Lond.

G.—Mr. H. L. Gill, Halifax; G. A.; Glasgow Union, Clerk of; Great Eastern Railway Co., Lond., *Continental Manager of;* G. J. S.; Mr. E. Gooch, Lond.; G. T. A.; G. M. S.

H.—Dr. L. K. Harrison, Leicester; Herefordshire General Hospital, Hereford, Secretary of; H. E. S.; Dr. E. F. H. Hardenberg, Watford; H. B. W.; Major M. P. Holt, R.A.M.C., Dublin; H. M.; Mr. T. W. Hughes, Abersoch.

I.—Messrs. Ingram and Royle, Lond.

J.—Mr. Y. M. Jones-Humphreys, Cemmaes; J. K.; J. F. W.; J. W. F.; Messrs. Jewsbury and Brown, Manchester; J. H., Lond.

L.—Mr. R. C. Lucas, Lond.; Mr. H. Lowe, Crewe; Mr. R. H. Lucas, Bury St. Edmund's; David Lewis Northern Hospital, Liverpool; Mr. Lockwood, North Walsham; Leslie's, Ltd., Lond.

M.—Dr. G. Metcalfe, Spennymoor; Mr. R. H. Moffit, Aberaman; Mr. J. McMurtrie, Glasgow; Mr. J. Murray, Lond.; M. T.; Mr. E. C. Masser, Waschbach; Dr. J. [illegible] Dr. J. [illegible] Messrs. [illegible] Maltine [illegible] Lond.; [illegible] R.A.M.C., Taunton.

N.—National Provident Institution, Lond., Secretary of; North Staffs Infirmary, Hartshill, Secretary of; "Norman," Liverpool; Dr. A. E. Naish, Sheffield.

O.—Mr. J. E. O'Hara, Darwen; Mr. J. M. Owen, Fishguard.

P.—Portsmouth Guardians, Clerk of.

R.—Mr J. P. Ryan, Golden; R. A. W.; Lady Russell Reynolds, Lond.; Royal Infirmary, Newcastle-on-Tyne, Secretary of.

S.—Mr. B. R. Sawhney, Jammu, India; S. E. H., Hull; Dr. G. I. Stewart, Gillingham; Messrs. T. G. Scott and Son, Lond.; Messrs. W. B. Saunders and Co., Lond.; Mr. A. Stent, Lond.; Dr. R. A. Shaw, Blackburn; Dr. J. M. Stewart, Saltcoats; Springfield House, Bedford, Medical Superintendent of.

T.—Tiverton Infirmary, Matron of; T. E. F., Kingston-on-Thames; Dr. J. Taylor, Castlebay.

V.—Miss Vinter, Eastbourne; Staff-Surgeon A. H. H. Vizard, R.N., Lond.; Vinolia Co., Lond.; Dr. R. H. Vincent, Lond.

W.—Mr. F. Forbes Winslow, Gibraltar; Messrs. H. Wilson and Son, Lond.; Mr. W. Webb, Brentwood; Mr. C. Webb, Margate; Mr. E. S. Weymouth, Lond.; W. A. M.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

A Presidential Address

ON

REFLECTIONS SUGGESTED BY THE NEW THEORY OF MATTER.

Delivered before the British Association for the Advancement of Science at Cambridge on August 17th, 1904,

BY THE RIGHT HON. A. J. BALFOUR, D.C.L., LL.D., M.P., F.R.S.,

FIRST LORD OF THE TREASURY AND CHANCELLOR OF THE UNIVERSITY OF EDINBURGH.

[Mr. Balfour commenced his address by remarking that since the British Association exists for the advancement of science it is well that now and again the place of gathering should be in some spot where science rather than its applications, knowledge, not utility, are the ends to which research is primarily directed and, that being so, surely no happier selection could have been made than the quiet courts of the ancient University, where "we tread the classic ground of physical discovery." After referring to "the illustrious line of physicists who have learned or taught within a few hundred yards of this building—a line stretching from Newton in the seventeenth century, through Cavendish in the eighteenth, through Young, Stokes, and Maxwell in the nineteenth, through Kelvin who embodies an epoch in himself, down to Rayleigh, Larmor, J. J. Thomson, and the scientific school centred in the Cavendish Laboratory," he proceeded :]

Now, what is the task which these men and their illustrious fellow-labourers out of all lands have set themselves to accomplish? To what end have led the "new and fruitful physical conceptions" which they have founded? It is often described as the discovery of the "laws connecting phenomena." But this is certainly a misleading and, in my opinion, a very inadequate account of the subject. To begin with, it is not only inconvenient but confusing to describe as "phenomena" things which do not appear, which never have appeared, and which never can appear to beings so poorly provided as ourselves with the apparatus of sense perception. But apart from this, which is a linguistic error too deeply rooted to be easily exterminated, is it not most accurate in substance to say that a knowledge of Nature's laws is all we seek when investigating Nature? The physicist looks for something more than what by any stretch of language can be described as "co-existences" and "sequences" between so-called "phenomena." He seeks for something deeper than the laws connecting possible objects of experience. His object is physical reality—a reality which may or may not be capable of direct perception; a reality which is in any case independent of it; a reality which constitutes the permanent mechanism of that physical universe with which our immediate empirical connexion is so slight and so deceptive. That such a reality exists, though philosophers have doubted, is the unalterable faith of science; and were that faith *per impossibile* to perish under the assaults of critical speculation science, as men of science usually conceive it, would perish likewise. If this be so, if one of the tasks of science and, more particularly of physics, is to frame a conception of the physical universe in its inner reality, then any attempt to compare the different modes in which, at different epochs of scientific development, this intellectual picture has been drawn cannot fail to suggest questions of the deepest interest. True, I am precluded from dealing with such of these questions as are purely philosophical by the character of this occasion and with such of them as are purely scientific by my own incompetence. But some there may be sufficiently near the dividing line to induce the specialists who rule by right on either side of it to view with forgiving eyes any trespasses into their legitimate domain which I may be tempted during the next few minutes to commit. Let me then endeavour to compare the outlines of two such pictures, of which the first may be taken to represent the views prevalent towards the end of the eighteenth century, a little more than a hundred years from the publication of Newton's "Principia" and, roughly speaking, about midway between that epoch-making date and the present moment. I suppose that if at that period the average man of science had been asked to sketch his general conception of the physical universe he would probably have said that it essentially consisted of various sorts of ponderable matter, scattered in different combinations through space, exhibiting most varied aspects under the influence of chemical affinity and temperature, but through

simple law. To this ponderable matter he would (in spite of Rumford) have probably added the so-called "imponderable" heat, then often ranked among the elements, together with the two "electrical fluids" and the corpuscular emanation supposed to constitute light. In the universe as thus conceived the most important forms of action between its constituents was action at a distance; the principle of the conservation of energy was, in any general form, undreamed of; electricity and magnetism, though already the subjects of important investigation, played no great part in the Whole of things; nor was a diffused ether required to complete the machinery of the universe.

Within a few months, however, of the date assigned for these deliverances of our hypothetical physicist came an addition to this general conception of the world, destined profoundly to modify it. About 100 years ago Young opened, or re-opened, the great controversy which finally established the undulatory theory of light and with it a belief in an interstellar medium by which undulations could be conveyed. But this discovery involved much more than the substitution of a theory of light which was consistent with the facts for one which was not, since here was the first authentic introduction[1] into the scientific world-picture of a new and prodigious constituent—a constituent which has altered, and is still altering, the whole balance (so to speak) of the composition. Unending space, thinly strewn with suns and satellites, made or in the making, supplied sufficient material for the mechanism of the heavens as conceived by Laplace. Unending space filled with a continuous medium was a very different affair and gave promise of strange developments. It could not be supposed that the ether, if its reality were once admitted, existed only to convey through interstellar regions the vibrations which happen to stimulate the optic nerve of man. Invented originally to fulfil this function, to this it could never be confined. And accordingly, as everyone now knows, things which, from the point of view of sense perception, are as distinct as light and radiant heat and things to which sense perception makes no response like the electric waves of wireless telegraphy,[2] intrinsically differ, *not in kind, but in magnitude alone.* This, however, is not all or nearly all. If we jump over the century which separates 1804 from 1904 and attempt to give in outline the world picture as it now presents itself to some leaders of contemporary speculation we shall find that in the interval it has been modified, not merely by such far-reaching discoveries as the atomic and molecular composition of ordinary matter, the kinetic theory of gases, and the laws of the conservation and dissipation of energy, but by the more and more important part which electricity and the ether occupy in any representation of ultimate physical reality. Electricity was no more to the natural philosophers in the year 1700 than the hidden cause of an insignificant phenomenon.[3] It was known, and had long been known, that such things as amber and glass could be made to attract light objects brought into their neighbourhood, yet it was about 50 years before the effects of electricity were perceived in the thunderstorm. It was about 100 years before it was detected in the form of a current. It was about 120 years before it was connected with magnetism; about 170 years before it was connected with light and ethereal radiation.

But to-day there are those who regard gross matter, the matter of everyday experience, as the mere appearance of which electricity is the physical basis: who think that the elementary atom of the chemist, itself far beyond the limits of direct perception, is but a connected system of monads or sub-atoms which are not electrified matter but are electricity itself; that these systems differ in the number of monads which they contain, in their arrangement, and in their motion relative to each other and to the ether; that on these differences, and on these differences alone, depend the various qualities of what have hitherto been regarded as indivisible and elementary atoms; and that while in most cases these atomic systems may retain their equilibrium for periods which, compared with such astronomical processes as the cooling of a sun, may seem almost eternal, they are not less obedient to the law of change than the everlasting heavens themselves.

---

[1] The hypothesis of an ether was, of course, not new. But before Young and Fresnel it cannot be said to have been established.

[2] First known through the theoretical work of Maxwell and the experiments of Hers.

[3] The *modern* history of electricity begins with Gilbert, but I have throughout confined my observations to the post-Newtonian period.

But if gross matter be a grouping of atoms, and if atoms be systems of electrical monads, what are these electrical monads? It may be that, as Professor Larmor has suggested, they are but a modification of the universal ether, a modification roughly comparable to a knot in a medium which is inextensible, incompressible, and continuous. But whether this final unification be accepted or not, it is certain that these monads cannot be considered apart from the ether. It is on their interaction with the ether that their qualities depend and without the ether an electric theory of matter is impossible. Surely we have here a very extraordinary revolution. Two centuries ago electricity seemed but a scientific toy. It is now thought by many to constitute the reality of which matter is but the sensible expression. It is but a century ago that the title of an ether to a place among the constituents of the universe was authentically established. It seems possible now that it may be the stuff out of which that universe is wholly built.

[After referring to the origin and development of suns and the gradual dissipation of the energy which during this process of concentration has largely taken the form of light and radiant heat Mr. Balfour proceeded :]

My present purpose requires me to do no more than observe that, be the theory of the primary and secondary qualities of matter good or bad, it is the one on which science has in the main proceeded. It was with matter thus conceived that Newton experimented. To it he applied his laws of motion; of it he predicated universal gravitation. Nor was the case greatly altered when science became as much preoccupied with the movements of molecules as it was with those of planets. For molecules and atoms, whatever else might be said of them, were at least pieces of matter, and, like other pieces of matter, possessed those "primary" qualities supposed to be characteristic of all matter, whether found in large masses or in small. But the electric theory which we have been considering carries us into a new region altogether. It does not confine itself to accounting for the secondary qualities by the primary or the behaviour of matter in bulk by the behaviour of matter in atoms; it analyses matter, whether molar or molecular, into something which is not matter at all. The atom is now no more than the relatively vast theatre of operations in which minute monads perform their orderly evolutions, while the monads themselves are not regarded as units of matter but as units of electricity, so that matter is not merely explained but is explained away. Now the point to which I desire to call attention is not to be sought in the great divergence between matter as thus conceived by the physicist and matter as the ordinary man supposes himself to know it, between matter as it is perceived and matter as it really is, but to the fact that the first of these two quite inconsistent views is wholly based on the second. *This is surely something of a paradox.* We claim to found all our scientific opinions on experience; and the experience on which we found our theories of the physical universe is our *sense perception* of that universe. That *is* experience; and in this region of belief there is no other. Yet the conclusions which thus profess to be entirely founded upon experience are to all appearance fundamentally opposed to it; our knowledge of reality is based upon illusion, and the very conceptions we use in describing it to others, or in thinking of it ourselves, are abstracted from anthropomorphic fancies which science forbids us to believe and Nature compels us to employ. We here touch the fringe of a series of problems with which inductive logic ought to deal, but which that most unsatisfactory branch of philosophy has systematically ignored. This is no fault of men of science. They are occupied in the task of making discoveries, not in that of analysing the fundamental presuppositions which the very possibility of making discoveries implies. Neither is it the fault of transcendental metaphysicians. Their speculations flourish on a different level of thought; their interest in a philosophy of nature is lukewarm; and howsoever the questions in which they are chiefly concerned be answered it is by no means certain that the answers will leave the humbler difficulties at which I have hinted either nearer to, or further from, a solution. But though men of science and idealists stand acquitted the same can hardly be said of empirical philosophers. So far from solving the problem they seem scarcely to have understood that there was a problem to be solved. Led astray by a misconception to which I have already referred, believing that science was concerned only with (so-called) "phenomena," that it had done all that it could be asked to do if it accounted for the sequence of our individual sensations, that it was concerned only with the "laws of Nature" and not with the inner character of the physical reality; disbelieving, indeed, that any such physical reality does in truth exist; it has never felt called upon seriously to consider what are the actual methods by which science attains its results and how those methods are to be justified. If anyone, for example, will take up Mill's logic, with its "sequences and coexistences between phenomena," its "method of difference," its "method of agreement," and the rest; if he will then compare the actual doctrines of science with this version of the mode in which those doctrines have been arrived at he will soon be convinced of the exceedingly thin intellectual fare which has been hitherto served out to us under the imposing title of Inductive Theory. There is an added emphasis given to these reflections by a train of thought which has long interested me, though I acknowledge that it never seems to have interested anyone else. Observe, then, that in order of logic sense perceptions supply the premisses from which we draw all our knowledge of the physical world. It is they which tell us there *is* a physical world; it is on their authority that we learn its character. But in order of causation they are effects due (in part) to the constitution of our organs of sense. What we see depends, not merely on what there is to be seen, but on our eyes. What we hear depends not merely on what there is to hear, but on our ears. Now, eyes and ears, and all the mechanism of perception, have, as we know, been evolve in us and our brute progenitors by the slow operati of natural selection. And what is true of sense percepti is, of course, also true of the intellectual powers whi enable us to erect upon the frail and narrow platform whi sense perception provides the proud fabric of the science Now natural selection only works through utility. encourages aptitudes useful to their possessor or his speci in the struggle for existence, and, for a similar reason, it apt to discourage useless aptitudes, however interesting th may be from other points of view, because, being useless, th are probably burdensome.

But it is certain that our powers of sense perception and calculation were fully developed ages before they we effectively employed in searching out the secrets of physic reality—for our discoveries in this field are the triumphs b of yesterday. The blind forces of natural selection, which admirably simulate design when they are providing for present need, possess no power of prevision and could nev except by accident, have endowed mankind, while in t making, with a physiological or mental outfit adapted to t higher physical investigations. So far as natural scien can tell us every quality of sense or intellect which does n help us to fight, to eat, and to bring up children is but by-product of the qualities which do. Our organs of sen perception were not given us for purposes of research, n was it to aid us in meting out the heavens or dividing t atom that our powers of calculation and analysis wer evolved from the rudimentary instincts of the animal. I is presumably due to these circumstances that the beliefs o all mankind about the material surroundings in which i dwells are not only imperfect but fundamentally wrong. It may seem singular that down to, say, five years ago our race has, without exception, lived and died in a world of illusions and that its illusions, or those with which we are here alone concerned, have not been about things remote or abstract, things transcendental or divine, but about what men see and handle, about those "plain matters of fact" among which common-sense daily moves with its most confident step and most self-satisfied smile. Presumably, however, this is either because too direct a vision of physical reality was a hindrance, not a help, in the struggle for existence, because falsehood was more useful than truth, or else because with so imperfect a material as living tissue no better results could be attained. But if this conclusion be accepted its consequences extend to other organs of knowledge besides those of perception. Not merely the senses, but the intellect, must be judged by it and it is hard to see why evolution, which has so lamentably failed to produce trustworthy instruments for obtaining the raw material of experience, should be credited with a larger measure of success in its provision of the physiological arrangements which condition reason in its endeavours to turn experience to account. Considerations like these, unless I have compressed them beyond the limits of intelligibility, do undoubtedly suggest a certain inevitable incoherence in any general scheme of thought which is built out of materials provided by natural science alone. Extend the boundaries of knowledge as you may; draw how you will the picture of the universe; reduce its infinite variety to the modes of a single space-filling ether; retrace its history to the birth of existing atoms; show how under the pressure of gravitation they became concentrated into nebulæ, into suns, and all the host of heaven; how, at least in one small planet, they combined to form organic compounds; how organic compounds became living things; how living things, developing along many different lines, gave birth at last to one superior race; how from this race arose, after many ages, a learned handful, who looked round on the world which thus blindly brought them into being, and judged it, and knew it for what it was:—perform, I say, all this and though you may indeed have attained to science in nowise will you have attained to a self-sufficing system of beliefs. One thing at least will remain, of which this long-drawn sequence of causes and effects gives no satisfying explanation—and that is knowledge itself. Natural science must ever regard knowledge as the product of irrational conditions, for in the last resort it knows no others. It must always regard knowledge as rational or else science itself disappears. In addition, therefore, to the difficulty of extracting from experience beliefs which experience contradicts, we are confronted with the difficulty of harmonising the pedigree of our beliefs with their title to authority. The more successful *we are in explaining their origin the more doubt we cast on* eir validity. The more imposing seems the scheme of hat we know, the more difficult it is to discover by hat ultimate criteria we claim to know it. Here, how-er, we touch the frontier beyond which physical science ssesses no jurisdiction. If the obscure and difficult region hich lies beyond is to be surveyed and made accessible, ilosophy, not science, must undertake the task. It is no isiness of this society. We meet here to promote the use of knowledge in one of its great divisions; we shall t help it by confusing the limits which usefully separate e division from another. It may, perhaps, be thought that have disregarded my own precept, that I have wilfully verstepped the ample bounds within which the searchers to nature carry on their labours. If it be so, I can only eg your forgiveness. My first desire has been to rouse in ose who, like myself, are no specialists in physics the same bsorbing interest which I feel in what is surely the most r-reaching speculation about the physical universe which s ever claimed experimental support, and if in so doing I ve been tempted to hint my own personal opinion that as atural science grows it leans more, not less, upon an lealistic interpretation of the universe even those who least gree may, perhaps, be prepared to pardon.

ROYAL CORNWALL INFIRMARY, TRURO.—The 05th annual report of this institution, which has just been issued, states that 392 in-patients were admitted during 1903, being seven less than in the previous year. The out-patients numbered 876, as compared with 937 in 1902. The average daily number of in-patients was 35, the average stay of each being 33 days. The cost per bed per annum was £58 16*s.* 11*d.*, an increase of over £4 as compared with the preceding year. The financial statement showed that the income was £2014 and the expenditure £2059.

ENTERIC FEVER AT TREGANTLE FORT, PLYMOUTH.—At the meeting of the St. Germans rural district council held on July 29th the deputy medical officer of health reported that five cases of enteric fever had occurred at Tregantle Fort. On visiting the farm at Kingdon, the proprietor of which supplies the fort with milk and also has the contract for removing sewage from the fort, the deputy medical officer found large quantities of sewage lying in the yard in close proximity to the dairy. He further discovered that the casks in which the sewage was removed were cleansed at the same well as the dairy utensils.

A Post-Graduate Lecture

ON

THE PATHOLOGY AND TREATMENT OF THE HERNIÆ OF CHILDREN AND THEIR RELATION TO CONDITIONS IN THE ADULT.

Delivered at the Hospital for Sick Children, Great Ormond-street,

BY EDRED M. CORNER, M.B., B.Sc. LOND., F.R.C.S. ENG.,

SURGE[illegible] THOMAS'S HOSPITAL AND
AS[illegible] FOR SICK CHILDREN,
[illegible] SON LECTURER TO
[illegible] S OF ENGLAND.

GENTLEMEN,—In selecting a subject for this lecture I have been desirous of bringing to your notice some points in connexion with some common disorder such as may be seen and tested almost on every day of practice. One of the most frequent ailments seen in the out-patient department has been taken for the material of this lecture. An endeavour has been made to throw light upon the origination, the treatment, and the after-effects upon adults. In this way I hope to convince you that childhood is the time when an operation has the best chance of curing a hernia, as then, and then only, is the surgeon's skill aided by nature in the subsequent growth of the subject. Childhood is the period when we may hope to do a little more than "put back the hands of the clock." We may be able to do a good deal towards the local "winding up again of that clock."

Amongst the out-patients who attend the practice of a hospital for children there are a large number of cases of hernia and so I have selected this opportunity of bringing before you several points of interest in their pathology and treatment which are largely new. It requires but little discrimination to see that there are two great factors in the production of herniæ in children. One, a predisposing condition is a congenital malformation by means of which the tunic [illegible] in co [illegible] sac, [illegible] viscera as can migrate. The second factor, the one which actively produces the hernia, is the association of herniæ in children with gastro-enteritis, or better, gastro-intestinal fermentation with the *production of gas*, the *consequent* distension of the abdomen and the increase of intra-abdominal pressure: As a result the weaker parts of the abdominal wall yield, one or more hernial protrusions appearing. It is quite common to see multiple herniæ in children, such as inguinal and umbilical, which are the consequences of this distension. The large hyper-resonant abdomen and the multiplicity of the results obviously point to the general rather than the local character of the method of the origination of these protrusions. The presence of rickets, the passage of offensive stools, &c., indicate the incapacity of the child to digest its food, whether the fault lies with the child, the food, or both.

THE HERNIÆ AND HYDROCELES OF CHILDREN.

In order to illustrate the relative importance of these two factors, the predisposing or passive and the active, I wish to call your attention *to the following points*. The first deals with respect to the very great frequency of the presence of a communication between the tunica vaginalis and the peritoneal cavity—i.e., the congenital hernia sac—which exists in the condition recognised as hydroceles in children (see Fig. 1). Careful inquiry or the direction of the mother's attention will reveal the fact that the hydrocele is less tense in the morning than it is at night—that is to say, after the child has been lying quietly and some o [illegible] through a communication fro [illegible] peritoneal cavity, the scrotal [illegible] again, the more frequently and [illegible] is looked for during the *course of an operation the more frequently it* is found. The presence of this strait or neck can be demonstrated, as a distinct thickening in the cord of that side, in the out-patient room.

Yet again, recent herniæ in adults are found to have congenital sacs. Therefore, the presence of a communication between the tunica vaginalis and the peritoneum alone is insufficient to cause the formation of a hernia. It would therefore seem, as would be expected, that the increase of intra-abdominal pressure, the active factor, is more important than the predisposing malformation. Again, when operating on the herniæ of young children the observer cannot but be impressed by the frequency of the occurrence of sacs of acquired or recent origin—i.e., unconnected with the tunica vaginalis. These considerations have led me to place the greatest importance on the gastro-intestinal fermentation in the causation and the production of herniæ in children and to look upon congenital malformations of the tunica vaginalis as merely important conditions predisposing thereto. Upon this view the importance of dietetics for the prevention of gastro-intestinal disturbances is still further emphasised. The relation of these infantile hydroceles to herniæ and gastro-intestinal troubles is one of the greatest importance, the result casting a lurid light upon the rationale of painting the scrotum with discutients in order to cure imperfections of digestion and the hernia sac of the hydrocele. Some observers have demonstrated the existence of fluid in the abdomina of children the subjects of hydroceles. The fact that these hydroceles are in hernia sacs, potentially so if they have never actually contained an abdominal viscus, demands that the treatment should be that of herniæ, which will be mentioned later, and demonstrates the utter futility of scrotal discutients.

HERNIÆ AND PHIMOSIS.

To students of text-books and recent monographs it will be at once apparent that no notice as yet has been taken of the almost universal and the most popular notion of the importance of phimosis in the causation of the herniæ of children. That such may be the case in some instances cannot be denied. But I have rarely seen a case in which I could satisfy myself that such was in reality true. The urinary opening in the prepuce is rarely so small as to be of such paramount importance. Also, in such a condition the prepuce itself would become ballooned and distended with urine during the act of micturition. Such a phenomenon would hardly be unnoticed by the mothers. Yet I have never been able to obtain such a history. Hence, with regard to the importance of phimosis in hernia production, it may be affirmed that, from the evidence before us, the prepuce is a much maligned structure and the operation of circumcision in this connexion one which raises false hopes. The operation by itself is certainly very rarely followed by any improvement in the condition of the hernia. Circumcision must be combined with other treatment, and though an operation and therefore of great importance in the eyes of the friends and the public, it should be pointed out that it is only of secondary value as compared with diet, medicine, &c. Doubtless this small operation is practised far more often than is necessary. In most cases it may be regarded in the light of a procedure of expediency rather than one of necessity. If more attention were paid it would be noticed that a small meatus urinarius in the small glans penis is very often associated with a tight prepuce and is the true cause of the child's straining during the act of micturition.

THE ADVANTAGES, DISADVANTAGES, AND THE VALUE OF TRUSSES.

To extend the above arguments further and so cover more fully the subject of hernia production in children it may be pointed out that it is the continuance or persistence of the increase of the intra-abdominal pressure, such as that arising from gastro-intestinal fermentation, which gives rise to the formation of a hernia rather than the sudden and more violent increments of pressure which arise from muscular efforts and strainings. In an adult the conditions seem rather to be reversed, as will be pointed out later.

The next point which I wish to bring before you is the curability of herniæ by means of a truss. The truss has long been a popular remedy for ruptures, and especially those of children. But it has not been made at all clear how this result is brought about. So far as can be ascertained it can cause matting of the tissues about the neck of the sac by means of the pressure which it exerts. And perhaps in a few instances it may also cause obliteration of the canal of the neck of the sac by means of the formation of peritoneal adhesions. The situation of these adhesions will be well below the level of the peritoneum and therefore will at best be comparable to the bad application of a ligature to the sac. Besides, by preventing the descent of abdominal viscera it will prevent further distension of the sac and enable natural growth to assist in, and perhaps perpetuate, the "cure."

The most popular truss for babies and young children is the one constructed out of a skein of wool. It requires but little experience of it to demonstrate the general inefficacy of this form of truss. Still, it is of some use. The pressure of this soft truss is quite insufficient to bring about the obliteration of the channel of communication in the neck of the sac. So that there can be no hope of curing the hernia by means of the formation of adhesions—that is to say, according to the ordinarily accepted method as delineated above. The second favourite is a spring truss which consists of a girdle and a pad, somewhat like those used on adults. There are two main objections to the use of this truss. First, the child is growing and the truss never fits for any length of time, having to be replaced by a new one. Secondly, as its pressure will be exerted on the structures of the spermatic cord as well as on the neck of the hernia, it will cause injury to the testis. Trusses used by adults occasionally give rise to orchitis in a subacute form; more commonly to fibrosis of the testis, which is the result of obstruction to the venous return. But the question assumes quite a different aspect when dealing with the interference with the blood-supply of a developing gland tissue such as that of the testis of a child. Orchitis, atrophy, and hardening by fibrosis, which will cause growth in the organ to cease, have been illustrated by cases among the out-patients. The importance to the individual of the testes before puberty has been strongly insisted upon in the lecture which I gave here in October, 1903.[1] And as the subject is one the importance of which has never been appreciated, it is yet again insisted upon. The value of the testes from the point of view of continuance of the race lies in their capacity for spermatogenesis. But, especially for the individual, there is another factor—namely, the perfecting rather than the origination of the male characteristics, the so-called secondary sexual characters, such as the male form and strength of body, the beard and moustache, the voice, &c., which are supposed to need for their perfecting some internal secretion of the testicle. If one studies people with imperfectly descended testes the conclusion that one must come to is that the perfection of the male characters may be estimated by the amount of perfect testicular tissue present. Many surgeons have referred in a light vein to the apparent prodigality of nature in the presence of bilateral organs in the male when one will insure the perpetuation of the race. The whole question turns on the fact that the production of spermatozoa is but one of the functions of the testicle. It is the external secretion. It is a fact amply proved that the presence of one good testis will insure spermatogenesis, and a little further study will convince the observer that the early atrophy of one testis will lead to some imperfection of the male peculiarities, such as deficiency of the growth of hair on the face, the high-pitched voice, &c., and the earlier the age at which the atrophy occurs the more marked will be the deficiences. After puberty—i.e., when once these characters are developed—they seem to be more or less permanent, no matter the subsequent conditions of the testes.

From the above it will be seen that considerable evil may result to the individual from the application of a too forcible truss, on account of its interference with the blood supply *of the delicate tissue of the growing testis* This being so it seems that it will be impossible to cure a hernia which has a congenital sac, that is to say one in which the tunica vaginalis and the peritoneum are continuous by means of a truss which will cause no injury to the testis unless the natural separation of these structures which normally occurs before birth is merely belated Yet it is known that a number of the herniæ in children disappear and are cured What is the explanation?

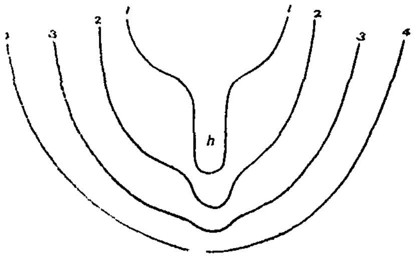
---

[1] Brit. Med. Jour., June 4th, 1904.

From what has been said above it may be presumed that the herniæ which are cured have not congenital sacs, these being apparently incurable short of operation And our experience at the operating table has already led us to *believe that acquired sacs are a great deal more frequent in* childhood than is supposed It may therefore be suspected that the cases in which the hernia becomes cured are instances in which the sac has been of acquired origin It is possible though improbable that these sacs can be cured by the obliteration of the neck of the sac by means of a truss, the pressure of which is such as not to injure the testis But it struck me that there was another possible and probable explanation for this fact and one which was of more extensive application

The acquired hernia sac of children is produced largely if not entirely by the increased abdominal pressure caused by gas formation due to fermentation in the intestines When this fermentation subsides under treatment or otherwise the original cause of the protrusion ceases to exist Now, as the child grows the concurrent increase in size and capacity of the body will lead to the retraction of the acquired hernia sac into the abdomen in this way it may be pulled right up and the hernia cease to exist (see Fig 2) The absence of a sac in the internal abdominal ring and the non protrusion viscera will enable that ring to grow normally and correctly the growth correcting the deformity which has resulted from the hernia, exactly as it does in the case of the curvatures of bones It is, in the nature of things, not easy to bring forward positive or direct evidence in favour of this hypothesis and I merely indicate the sources of evidence from which the conclusions was drawn

FIG 2



To illustrate the retraction of *h* an acquired hernial sac during successive phases (1 2, 3 4) of the growth of the child

1 I have seen the apparent complete disappearance of inguinal hernia in a child in which the testis was quite separate from the hernia, presumably therefore, the sac was an acquired one This I have seen occur in cases treated both with and without the use of a truss Cure has been seen in both sexes

2 *I have operated upon a case in which there has been* a most distinct history of a hernia in childhood without finding any trace of it This case was that of a woman between 25 and 30 years of age who had been advised to undergo an operation on the supposition that a hernia was then present No sign of its presence could be detected and operation was performed in order to satisfy the patient s mind A careful examination at the operation yielded no trace of the presence of a sac in the inguinal canal What had become of the sac? My contention is that growth had drawn it up into the abdomen The descent of the bladder and the uterus into the pelvis, which are in the abdomen in the child will also play some part in the natural reduction of a hernia in the female sex during the period of growth

3 I have more than once operated upon the varicoceles of young men who had, so far as can be proved, a certain history of having had a hernia when children and at the operation no trace of the existence of a sac could be found In these cases the hernia had only been present up to an early age and they contrast well with the following case, in which the hernia persisted for six or seven years

4 In St Thomas s Home I operated upon a man, aged 21 years for the radical cure of an inguinal hernia which had appeared within the last few weeks He gave a very definite history of having had a hernia in the same situation from the age of one year until between those of seven and eight—that is to say for a period of between six and seven years From this age until quite recently for a period of 14 years the rupture was cured ' Then a hernia of *smaller dimensions as far as its relations with the scrotum* were concerned made its appearance At the operation the sac was thin and easily separated from the structures of the spermatic cord showing all the evidences of its being of recent origin It was of the acquired variety, having no connexion with the tunica vaginalis There was no trace of the former sac Where had it disappeared to?

The above cases offer some evidence in favour of the suggestion of the disappearance and retraction of acquired hernia sacs during the period of growth But if my suggestion of the natural cure of acquired hernia sacs by these means is true a somewhat similar occurrence should take place when there is a congenital sac—that is to say, when the tunica vaginalis and the peritoneal cavity are in communication so causing the late appearance of imperfect descent of the testis Upon this I can say but little but I have distinctly obtained the history that a boy s testicle was in its proper place when a baby, but later it had become imperfectly descended It cannot be assumed that this was the natural result of growth though I can add the further evidence that at the operation the imperfectly descended testis was accompanied by a congenital hernia sac This distinctly suggests the explanation which has been offered, natural growth retracting into the abdomen the hernia sac, and at the same time offers another example of the new class of acquired or secondarily imperfectly descended testes

If these views are accepted there must be a considerable modification of our methods of treatment There are two main lines to be followed, as indicated in the passive or predisposing and the active agents in the formation of herniæ In the first place to deal with the great predisposing factor in the formation of herniæ in children, we cannot prevent the occurrence of congenital malformations As trusses are likely to be useless in this instance, if not mischievous nothing short of operation is likely to cure a hernia which has a congenital sac It is the hernia with the acquired sac which offers more scope for success in non operative treatment The factor in the production of these is the active one—namely, the increase of intra abdominal *pressure due to gastro intestinal fermentation* Hence the value of the diagnosis as to which sac is present Naturally, the real treatment of the case should be relegated to the physician as that of the surgeon consists of merely preventing the hernia coming down by the use of a woollen or other light truss and the recumbent position if necessary By attention to the diet the physician can do a great deal towards both the cure and the prevention of herniæ With an acquired sac the treatment must first consist of attention to diet the administration of purgatives and other intestinal cleansing agents combined with recumbency and the use of a truss of a light description The public will have to be educated to the fact that herniæ in children may require rest in bed as much as do more acute and apparent illnesses With the above *treatment a considerable number of herniæ* of children with acquired sacs can be cured in a natural manner by the growth of the child

THE DEFORMITY OF THE INTERNAL ABDOMINAL RING CONSEQUENT UPON THE PRESENCE OF A HERNIA DURING CHILDHOOD

The next question to be considered is How long and up to what age should this treatment be continued? To shed light upon this point a very interesting case can be brought forward which admirably illustrates the malformation of the internal abdominal ring which results from the prolonged presence within it of a hernia during the period of growth

An athletic and strongly made man, aged 21 years had had a rupture from *the age of one year until between the a* of seven and eight—that is to say, for a period of between six and seven years during the time of active growth of the body. For 14 years he remained quite cured and came to me at the age of 21 years on account of the recent appearance of a hernia at the same place. The size and the condition of the hernial sac confirmed the history of its recent origin and have been already detailed. The second stage of the operation, the suture of the internal abdominal ring, was *not at all easy*. It was this difficulty which attracted my attention to the condition. The shape of the hernial opening was more or less circular, whilst it should have been slit-like, allowing of valvular closure of the inguinal canal by the contraction of the abdominal muscles, which protective condition was in this instance impossible. And the fact that the patient had had 14 years of freedom from the rupture was entirely due to his naturally strong tissues rather than to any safeguarding mechanism of his inguinal canal. Considerable difficulty was experienced in effecting closure of the internal ring and a stronger silk than usual had to be used for it. The rest of the history of the case has been one of perfect success so far and only interests the patient, his friends and relatives, and myself, so that no more details will be given.

FIG. 3.

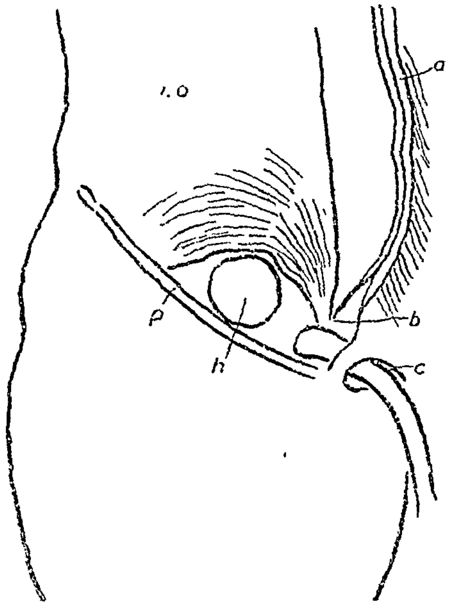


Illustration of the deformity of the internal abdominal ring caused by the presence of a hernia for 7 years during childhood—i.e., the period of growth. I. O., Internal oblique muscle. *a*, Flap of external oblique muscle. *b*, Conjoined tendon. *c*, External ring. *h*, Hernial orifice at internal ring. *p*, Poupart's ligament.

The great interest of this case lies in the interpretation of the deformity of the internal abdominal ring. The obvious suggestion is that it is dependent upon the presence of a hernia passing through it for a period of from six to seven years (see Fig. 3). The fact that the rupture occupied it would have prevented the ring from "growing straight." The relative growths of the internal abdominal ring and "the hole in it for the rupture" would be unequal, as the former would increase in size *pari passu* with the growth of the body, whilst the latter would become smaller until the hernia was "cured." At the time of the final disappearance of the hernia there would be left a relatively small hole within the internal abdominal ring, more or less circular in outline, perhaps with rather hard and unyielding edges. Consequently a distinction is made obvious between the internal abdominal ring and the aperture in it which serves for the passage of the hernia. This difference is not met with in the ordinary acquired herniæ of adults or in the congenital herniæ of young children. Correlated with this there is a development of a few fibres of the internal oblique attached to the part of Poupart's ligament below the limit of the usual origin of that muscle. The internal abdominal ring and the "aperture hernia" then seem to be the same.

this case I have operated upon a boy in the for Sick Children, Great Ormond-street, nearly eight years of age, who had inguinal hernia which had "not been properly cured since birth." At the operation he was found to have an acquired hernial sac, and there was a similar though naturally less marked deformity of his internal abdominal ring. On looking through my notes for cases in which difficulty had been encountered in suturing the internal abdominal ring I found another case in which there had been a persistent hernia during the period of growth. It would therefore seem that this malformation is quite well marked and in certain degrees may be easily recognised. The existence of such a malformation (which completely abolishes any valvular and protective action on the part of the muscles which enter into the formation of the inguinal canal) and its consequences, *point very plainly to the fact that there should be* a recognised limit to the non-operative treatment of hernia during the period of active growth before the deformity will have become permanent, as it is not right to continue a treatment which will lead to a permanent deformation of the internal abdominal ring and perhaps to the formation of a hernia later in life. There may also be mentioned from the surgeon's point of view, as later the case will be very likely to come into his hands, that there is the resulting difficulty in suturing the internal abdominal ring owing to the unyielding character of the margins of the hernial aperture, and therefore the performance of a satisfactory "radical cure" becomes difficult. The contemporaneous existence of a gross pathological process during the period of active growth and the consequent results of its action on the latter constitute a most important feature in the surgical diseases of children.

TREATMENT.

For the treatment of the herniæ of infants or children I would suggest the following lines :—

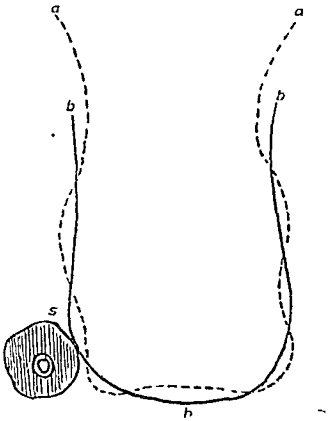
1. Treat with dieting, rest in bed if necessary, a light truss, and grey powder or the like, all herniæ up to the age of four or five years. The selection of this time is quite arbitrary and the proper age limit must be selected for each individual subject. Female children can naturally be treated with more effective trusses than male. Exceptions must be made of the following: (*a*) large or uncontrollable herniæ; (*b*) irreducible, perhaps difficult reducible or incarcerated, herniæ; and (*c*) strangulated herniæ. In these it is better not to delay operative procedures. Many of the difficult reducible herniæ of children are caused by the cæcum on the right side sliding into the hernia sac without a complete peritoneal investment. This condition is called hernia *en glissade*.

2. At the age of four years or thereabouts all herniæ of children should be submitted to operation unless there are special circumstances. Particular mention may be made of: (*a*) those with a congenital sac (the operation is now performed at the age of election); (*b*) those with an imperfectly descended testis; and (*c*) those which have been, and apparently will be, persistent in character.

It may be added that this age, four or thereabouts, has been selected as the least in the way of operative interference is then required, the internal abdominal ring will grow correctly afterwards, it is easier to perform the operation at this age than earlier, and finally, I believe that the most radical operation—i.e., with the best prognosis—can be done then which the subject's tissues will ever permit, nature, solely during the period of growth, aiding the process for cure. An eminent surgeon has claimed that the operation of cure for hernia merely puts back "the hands of the clock" as regards that condition. At the age for operation which is being advocated more can be done, as subsequent growth will aid in the cure and help to give permanence to the surgeon's work.

There are two points in the operation to which attention may be directed. The usual method of dealing with the sac is to strip it up and ligature the neck, after having divided it if a congenital one. Such a procedure is not without danger to the vas deferens and the spermatic veins such as might lead to results which may cause cessation of growth and development in the testicle. It is therefore not always advisable to adopt the ordinary method, and to meet the difficulty I have adopted the following measures. The sac is opened longitudinally and any contents therein are returned to the abdomen. A purse-string suture is carefully inserted, taking only the sac wall, as high up as is practicable. This is then tied occluding the opening of the sac. The hernia sac or the tunica vaginalis is left as widely open as possible. The question as to whether it is desirable or not to open up the inguinal canal and suture the internal abdominal ring seems to depend upon the size and the persistence of the hernia and the age of the child. The larger the hernia, the longer the history of its presence, the older the child—all indicate the advisability of the suturing of the internal abdominal ring. It may be laid down that when there is any doubt as to the performance of this step in the operation it had better be done. No harm but only good is likely to result locally.

FIG. 4



Illustrating method of ligation of the sac. *a, a*, Represent ligature passed. *b, b, b*, The sac. *s* Is the spermatic cord.

RELATIONSHIP BETWEEN THE HERNIÆ OF CHILDREN AND ADULTS

There must be some relation between the herniæ of adults and those of children. This is a subject about which there is as yet but little known. It is quite recognised that people who have had herniæ as children sometimes have a recurrence later in life, as was so in the case which has been quoted at some length in this lecture. Adults who have had hernia when young and who have no further trouble do not come under our observation and therefore we know far less about them. But this latter class must in reality be a fairly large one. One would expect that it would be mainly derived from those cases in which the hernia was present only in the early months of life, was only in evidence for a short time, and had an acquired sac. In point of fact, the *earlier the appearance* and the shorter *the duration of the* existence of a rupture the more likely it is to be cured by natural means.

As a contrast to these there are instances in which the hernia appeared late in childhood or persisted until that time. It is the persistence of the rupture which leads to the permanent deformity of the internal abdominal ring, a result which need never occur if only the hernia is treated actively by operation at an early age. And on this account it seems advisable that ruptures in children—i.e., during the period of active growth and before heavy muscular strains are indulged in—should not be left too long. For generations there has been a cry that surgery should aid nature. During childhood is the only time at which the surgeon has nature to help him in his attempts to cure herniæ. Hence it seems that this will be the time of life when the prognosis will be the best and should be the age of election for the success of an operation. Throughout I would urge the advisability of the diagnosis being made between the congenital and the acquired sacs of herniæ. It seems more than doubtful if the former—congenital sacs—can ever be cured by any measures short of "division and ligature" of the sac, whilst, as has been pointed out, those with the acquired sacs have a very fair chance of being permanently cured by the purely natural means of healthy growth and should only be interfered with operatively for their persistence, their size and incontrollability, their developing acute symptoms, or for any special reasons, such as the presence of an imperfectly descended testis, &c.

To return to those herniæ which have congenital sacs. At present there is little evidence that the canal of the neck of the sac ever becomes obliterated by a natural process which has been delayed, such as that which normally occurs before birth. Personally, I firmly believe that such a belated natural process does occur, and for evidence of it I would instance the cure of the hydroceles of babies which originally have patent communications with the peritoneum. Of course, this is no direct proof, but it affords some basis upon which one can rest an act of philosophic faith. If this communication persists up to the "age of election," from four to five, the case of hydrocele had better be operated on just as if it was a hernia. Nor is it right to use a truss which exerts sufficient pressure on the neck of the sac to lead to its closure by means of the formation of peritoneal *adhesions on account of the fact that the self same pressure* will act also on the nutrient vessels of the developing testis, and so cause such pathological changes as will hinder or entirely prevent the future perfecting of that organ.

There is yet another problem to which attention must be directed. Can the abdominal distension of a child if it persists exert any deleterious action upon the hernial regions during their growth, short of the actual formation of a hernia, which can predispose to such a development in the adult? Long-continued abdominal distension during the period of growth may bring about a lax and weakly condition of the region of the hernial rings. And I cannot help thinking that the seeds of future hernia formation are sown during infancy and childhood far more often than we suspect. We are all familiar with the large, loose, lax inguinal rings of adults so frequently found in which no definite herniæ are felt. How is it that these rings come to be so large? Is it because they are congenitally so? or is it that they are the result of persistent distension of the abdomen during childhood? There seems no doubt but that we *must favour the* latter hypothesis, though the *former may* be true in some rare instances. These large rings have a counterpart in the divarication of the recti so often seen in children with distended abdomina. Persistent abdominal distension in children will lead to the abolition of the protective valvular muscular arrangement of the inguinal canal, which condition may persist in adults and lead to the subsequent formation of herniæ.

It is to be hoped that the subject of the relationship which exists between persistent abdominal distension or the actual occurrence of hernia during infancy and childhood and the herniæ of adults has been clearly put before you so that the question may receive more attention in the future than it has done in the past. And let us hope that medicine and surgery in childhood will do much to abolish these complaints in the adult. It is curious, or better, unusual, that in a lecture on surgery medicine should be so strongly advocated. But anyone who attends upon our out-patient department will not be able to resist the conclusion that intestinal distension by the gases formed by fermentation is the most important factor in the actual production of a hernia in a child and, let us suggest, possibly also in the adult. A similar relation may, and probably does, exist between the hydrocele of a child and the hernia of the adult in a lesser degree.

To sum up, this lecture has been utilised to urge upon you the possibility, if not the fact, that if only more attention is paid to the diet and the persistence of abdominal distension of children, the advisability or not of operative interference for all herniæ in children which are persistent or of which the subjects are above the age of five years, the diagnosis between the acquired and congenital hernia sac, and active treatment adopted during childhood, far fewer adults will be handicapped by that common disadvantage—namely, a hernia.

UMBILICAL AND VENTRAL HERNIÆ

Finally, before this lecture is concluded, reference must be made to the umbilical and ventral hernia of children which illustrate admirably in a form which will be readily accepted many of the points, problems, and principles which I have advocated with inguinal herniæ. To begin with, the fact that these herniæ—umbilical and ventral—are correlated causally with persistent distension of the abdomen will be more readily agreed to than it is in the case of those in the inguinal region. Also, it is well recognised that if the distension is relieved and no visceral protrusions are allowed to occur these herniæ may be cured. And I think that people will be more ready to accept my suggestion that the growth of the trunk retracts the peritoneal sac of the hernia within the abdomen and so "cures" the rupture in a natural way. The views put forward and derived from a study of inguinal herniæ, in point of fact, seem more likely to meet with acceptance in their application to the umbilical and ventral protrusions. In the latter situation the full force of the evil of the persistence of the hernia will be appreciated and also the necessity for operation before permanent deformity has been inflicted on the ring by the rupture. Likewise the natural cure and the restoration of the umbilical ring to its proper condition will meet with ready acceptance. It is merely necessary to point out that these herniæ exemplify all the points put forward in a previous section of the lecture. But it is advisable to point out one difference which umbilical herniæ exhibit. These ruptures are merely local manifestations of the effects of abdominal distension. The divarication of the recti muscles is another and one which always accompanies them, corresponding when alone to the large inguinal rings without herniæ, which, I have suggested, arise from abdominal distension and divarication in those situations. As a consequence, when operating for umbilical herniæ it is advisable to continue the suturing well above and below the navel, so as to do more than close merely the local manifestation.

ELECTROCUTION ON THE RAILWAY: THE DANGERS OF THE LIVE RAIL.

By THOMAS OLIVER, M.A. DURH., M.D & LL.D. GLASG., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

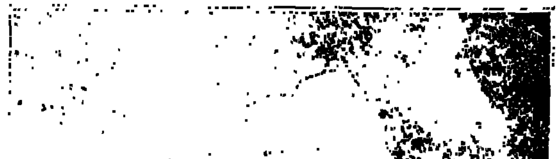
RECENTLY the attention of the public has been directed to the dangers of electric traction by the loss of life, human or other, that has been taking place upon our railways. Within the last few weeks the danger of the live rail has been made the occasion of questions in the House of Commons. On the Southport railway a short while ago a man met with his death through stepping upon the elevated rail; in the neighbourhood of Newcastle-upon-Tyne one child, three men, and numerous dogs have been killed by contact with the dangerous rail; while in other instances severe injuries have been received and death just averted as in the case about to be reported. There is not the least doubt as to the great advantages of electric traction upon the railway as a rapid and pleasant means of transport and few of us would like to see it altered, but it is quite apparent from the number of accidents which have already taken place that a sufficient protection is not afforded the public against its dangers. People will cross railway lines and animals will stray on to them. As the accidents just mentioned occurred in broad daylight, when people had all their senses to guide them, it is painful to contemplate what may be the dangers to human life during the long winter nights unless additional means are taken to inclose the elevated rail. It is no excuse on the part of a railway company to say that the people who met with their death thus on the railway were trespassing, for all the men who were killed were not guilty of this offence. In two instances the men, one of whom was provided with special boots, were railway servants, and even in cases where it is admitted that the victims were trespassers no such plea as that put forward by a railway company can altogether condone the fatal result since death is surely not, humanly speaking, the penalty of trespassing.

For the opportunity of publishing the notes of the following case I am indebted to Dr. R. A. Wilson of Wallsend, with whom I have seen the patient on two occasions.

On the afternoon of June 13th, 1904, rather a wet day, a man, aged 37 years, in crossing the line at Wallsend tripped upon the ordinary line and falling upon the current rail he struck the back and right side of his head. He was immediately rendered insensible. As the accident was seen by one of the railway servants this man at once put on india-rubber gloves and running to the rescue of the patient he pulled him off the track. The injured man was extremely rigid; his mouth was clenched and had to be opened forcibly by means of a piece of wood. Five or six minutes after the accident Dr. Wilson, who lives in the immediate vicinity, was on the spot. The man was then lying on the side of the railway; he was unconscious and was the subject of general convulsions. His jaws were firmly clenched; his eyes were fixed and staring, pupils normal and equal. The respiration was quickened but not deep. In the urgency of the moment the condition of the pulse was not registered. Artificial respiration, which had been begun, was maintained. For fully half an hour the patient remained in a state of unconsciousness, then there was a slight recovery followed by a relapse and a recommencement of the convulsions. Meanwhile a stretcher was procured. On the way to the man's home the convulsive movements were so severe that he frequently all but fell out of the ambulance. When the patient came to himself one and a half hours later there was complete anæsthesia; he had no feeling in any part of his body. As sensation returned his feelings were at first unpleasant. He complained of "pins and needles" all over him; this lasted for ten minutes. He was not sick but he felt dizzy and strange. Two hours after the accident he complained of pain in the right foot. On removing the boot the upper surface of the large toe and of that adjoining it was seen to be blistered; it was also red and angry looking. A large blister was also noticed on the heel. There was no difficulty with the bladder or rectum.

Two days afterwards when I saw him with Dr. Wilson he was fairly well in himself but the right foot showed signs of extensive burning. Both the upper and under surfaces of the big toe and of the two adjoining toes were blistered and vividly red round the edges. There was a superficial ulcer stretching for fully one inch across the sole of the foot just behind the toes, while towards the heel there was a blister three inches by two and a half, with red and swollen borders and extremely tender to the touch. A small burn with tender edges was also found on the back of the elbow, while over the upper part of the occipital bone there was a hard caked mass of blistered skin and incrusted exudation two inches in diameter and surrounded by a circle of superficial ulceration. The main features at this stage were the burnt appearance of the wounds—they looked angry and seemed as if they would slough (Fig. 1). It is interesting to

FIG. 1.



Burn on the heel and the under surface of the toes, the result of contact with "live rail." The appearances are those of a red[illegible] considerable reactive inflammati[illegible] The tissues look as if they wou[illegible]ken five days after the injury.

know in connexion with the extensive burns to the foot that the boot which the man was wearing at the time of the accident was not injured at all. I examined the boot carefully but it betrayed no sign whatever of having been the medium through which the electric current had passed [illegible] mark. The urine [illegible] 10th the wounds, instead of having made progress towards healing, looked worse. The ulcers were deeper and there was no healthy reaction on the part of the surrounding tissues. The under surface of the big toe looked as if it had been split open; the tissues were swollen and the exposed bone seemed as if it would necrose (Fig. 2). I was impressed by the great destruction of the tissues that had taken place and the absence of any attempt at healing nearly four weeks after the accident.

Electrical Currents and their Effects.

For the distribution of electricity into towns two kinds of currents are employed—the continuous and the alternating. The accidents produced by the two kinds of currents are not identical in all respects. The continuous current at high tension, coming into contact with the human body, causes burns and considerable disorganisation of the tissues. When the shock has been severe it nearly always causes death. With alternating currents burns also occur but they are usually less severe, while the destruction of the tissues is both less complete and not so widely diffused.

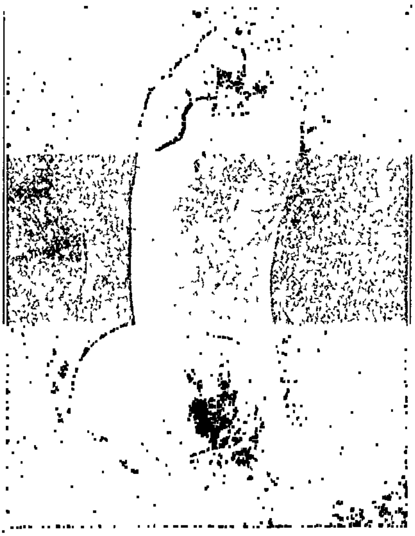
Experimental Evidence.

In 1885 Grange[1] reported two deaths from electric shock and made this circumstance the occasion for carrying out a series of experiments upon animals submitted to the influence of continuous currents. He attributed the death of animals thus dealt with to small hæmorrhages in the medulla oblongata, which he believed induced cessation of respiration and stoppage of the heart's action through excitation of the vagal centres. D'Arsonval, in a report presented to the Academy of Sciences in 1887, pointed out that electricity acted in two different ways—(1) by directly acting upon the tissues and destroying in an irremediable manner their physiological properties (*effets disruptifs*); and (2) by acting reflexly in an indirect manner and producing inhibition of the nerve centres which might or might not be of a fleeting character. In the latter case the main cause of death, he maintained, would be arrest of the breathing. At the Edison Laboratory, New York, experiments were carried out in 1889 by Brown, Kennelly, and Peterson[2] upon dogs, a horse, and two calves, the continuous and alternating currents being both employed. The alternating currents varied from 160 to 800 volts. These when applied for one second invariably caused death. The application of the continuous current, on the other hand, was not always lethal. Tatum,[3] in 1890, concluded from his experiments upon dogs that death was due to arrest of the heart's action. He demonstrated that neither the administration of atropine nor section of the pneumogastric nerves made the slightest difference, for when animals were exposed to a severe electric shock death still came through arrest of the heart's action. Tatum therefore attributed death in these circumstances to paralysis of the wall of the heart and not to any influence exercised by the current upon the nervous system.

In 1890 it was arranged by the legislature of the United States that criminals in that country were to be electrocuted by alternating currents of 1500 volts, from 15 to 30 cycles per second. In cases where the law was thus given effect to there was a general consensus of medical opinion that when the current was broken after a contact of several seconds the heart was found to be beating and that respiration re-established itself in such a manner as to oblige the executioner to make a fresh contact. In some of the criminals thus electrocuted Macdonald[4] found capillary hæmorrhages on the floor of the third and fourth ventricles of the brain but he admits that these lesions were not constant.

In 1896 Kratter[5] experimented upon a variety of animals with alternating currents and he came to the conclusion that death was due to paralysis of the respiratory centre and to asphyxia as a consequence. Kratter regarded as important elements the duration of the current and the kind of animal which he was employing. He found that guinea-pigs and rabbits resisted the shock better than dogs but on post-mortem examination no constant lesion was found. The blood was not altered nor did the nerve cells exhibit any appreciable change on microscopical examination.

FIG. 2.



Injury (burn) to foot, the result of contact with "live rail." The ulcers are deep and are surrounded by very unhealthy tissues. There is no sign of healing. Photographed on July 11th, 1904, 28 days after the injury.

In 1897 when serving on the Dangerous Trades Committee of the Home Office, one of the risky occupations referred to that committee was employment in electrical generating stations. To do justice to the inquiry I felt that it was desirable that fresh light if possible should be thrown upon the cause of death in electric shock. Accordingly, with the assistance of Dr. R. A. Bolam, my colleague in the physiological department of the College of Medicine, I carried out a series of experiments upon animals. The paper embodying the results of these experiments was published in 1898.[6] The animals employed were dogs and rabbits and the anæsthetic used was ether. Both the blood pressure and respiratory movements were recorded. An alternating current supply in the laboratory running at 100 volts and 100 cycles per second was transformed as required. Wet sponge electrodes efficiently insulated were applied to the fore and hind limbs of the animals on portions of skin previously shaved and thoroughly moistened. We found that when animals were exposed to electric currents of sufficiently high potential, death, practically speaking, was instantaneous. The animal was thrown into a state of opisthotonos during which breathing was suspended; the heart's beat was momentarily quickened and then arrested, while with currents of somewhat higher potential still it was immediately arrested without any preliminary quickening. In most of our experiments the organ first affected was the heart. Sometimes the breathing was observed to continue rhythmically after the heart had ceased beating. Only in the case of very high voltages with currents considerably above the potential usually required to kill an animal was there simultaneous stoppage of the heart and respiration. We never succeeded in causing primary arrest of the respiration followed by failure of the heart nor did we find that there was any absolute relation between the voltage employed and the death of the animal. A smaller animal, for example, was not killed by a lower voltage than an animal twice its size. Frequently it was the reverse of this. Circumstances suggested to us that the younger and the less highly organised the animal the higher often was the potential required to kill it when compared with that needed for an older animal.

Prevost and Battelli[7] of Geneva found that alternating currents of feeble tension—e.g., 120 volts—caused fibrillary tremor of the heart and that it was this circumstance which dominated all the other phenomena. The action of the heart was arrested after contact of one second. Occasionally there was a generalised tetanus with opisthotonos followed by clonic convulsions. Prevost and Battelli divided electrical currents into high, medium, and low, rather an arbitrary division on the whole. In dogs receiving 240 volts for two seconds the heart presented fibrillary tremor and there was generalised tetanus followed by complete arrest of respiration; with 600 volts for two seconds there was fibrillary tremor of the heart with convulsions but no respiratory movement; while with currents ranging from 240 to 600 volts there was produced in dogs simultaneous arrest of heart and respiration. These observers found (1) that currents of low tension produced paralysis of the heart; (2) that mean tension currents produced simultaneously paralysis of the heart and respiration; and (3) that high-tension currents caused principally nervous symptoms. The particular part of the body at which the electric current enters is of importance. Arrest of breathing and the development of convulsions were induced by a smaller voltage when the electrodes were applied to the head. The mode of death from continuous currents they found to be in the main similar to that brought about by alternating currents; also that currents of 550 volts caused rapid fall of arterial pressure due to paralysis of the heart.

D'Arsonval held the view that the continuous current was only risky to life when the circuit was broken, but most observers while admitting that the shock is more dangerous when the circuit is broken, yet are of opinion that closure of the circuit is equally dangerous. Battelli found that there was no exact relationship between the electrical energy necessary to cause the death of an animal and its weight, yet maintained, contrary to most observers, that young animals are more sensitive to the effects of electricity than those of maturer age.

R. H. Cunningham[8] of New York from his experiments concluded that although during the passage of the electric current there is respiratory standstill, yet the respiratory centre in the medulla is neither paralysed nor instantly killed, otherwise no natural rhythmical respiratory movements could occur after the circuit is broken. He found that the currents affected principally the left wall of the heart. There was cessation of the heart's beat upon closure of the circuit. Currents of from 110 to 120 voltages readily killed dogs when passed for one minute 16 seconds from the head to the thorax. The currents were equally fatal when carried through the thorax by attaching the electrodes to the forearms, or one to the left forearm and the other over the heart. Cunningham found that young, well-nourished, and hardy dogs withstood a slightly greater strength of current through the chest for a longer time than ill-nourished or older dogs and that the minimum strength of current required to stop the heart of different dogs bore no definite ratio to their size and weight. "Besides the influence exerted by the quality, duration, strength, and density of the current there must be some other factor, apparently residing in the heart and probably physiological in nature, which exercises an influence in the readiness with which the cardiac effect is produced." An enfeebled state of health, for example, may increase the susceptibility of an animal to electrical shock. In cases where men have received severe but not lethal shocks there has usually been before consciousness is lost a moment or two during which strange sensations have been experienced, not necessarily of pain but as if the muscles were all drawn and a sensation of tremendous pressure felt across the chest. Owing to the severity of the muscular spasms a man falling upon the live rail might be thrown in one or other direction, thus breaking his connexion with the live contact.

Voltage Required to Kill.

Opinions are divided as to the voltage required to kill. The professor of electrical engineering at University College, London, Dr. J. Ambrose Fleming, tells us that at one time he thought it was only high voltages that killed. This opinion he no longer holds. The peculiar circumstances operating at the time must be taken into consideration. Men may not be killed on brief contact with 2000 volts while contact with 500 may prove fatal. Railways run at from 300 to 600 volts and this is allowed by the Board of Trade in the belief that it is not dangerous. Experience does not confirm this opinion, as contact with lower voltages has shown again and again. In a public bath in London a man recently lost his life by accidentally placing his hands upon the electric light wires in which the pressure was only 250 volts, the same as in private houses. In this case the danger was increased owing to the man's hands being wet. The risks to workmen on the railway are intensified during wet weather. To these men the danger lies in placing one foot on the live rail while the other is on earth. As Professor Fleming says, "You may stand on a live rail or even sit or lie on it. ...... There is no danger so long as you are entirely on the rail. If you could be absolutely insulated from the earth there is probably no pressure of current that would do you any harm. The danger comes when one part of you, especially a bare part such as the hand or face, touches the live rail and some other part is in contact with the earth. That is where the 'live' rail constitutes so grave a danger." With railway lines in the open country the danger is not alone that cattle or sheep may stray upon them, but that the animals may be electrocuted and their bodies falling upon the track may become the cause of an accident to the train that follows. If the lives of the travelling public are to be safeguarded there must be adequate covering of the elevated rail, not only at stations and level crossings, but along the whole length of the track. The manner in which this rail should be protected is a matter for electrical and railway engineers. Gloves made of indiarubber should be worn by men who are proceeding to rescue the victims of electrical shock on a railway, and on carefully removing these unfortunate persons from contact with the elevated rail artificial respiration should be at once resorted to in cases of suspended animation and maintained for a considerable length of time, for more than half an hour if necessary. Cunningham recommends transfusion of defibrinated blood as an accompaniment to artificial respiration. This method of treatment has been followed by good results in his hands but it is evidently more likely to be adopted and to prove more successful in the laboratory than on a railway line for example.

ON THE ACTION OF VENOMS OF DIFFERENT SPECIES OF POISONOUS SNAKES ON THE NERVOUS SYSTEM.

By GEORGE LAMB, M.D. GLASG.,
CAPTAIN, I.M.S.; ASSISTANT DIRECTOR, PASTEUR INSTITUTE OF INDIA;

AND

WALTER K. HUNTER, M.D., D.SC., F.F.P.S. GLASG.,
ASSISTANT PHYSICIAN, GLASGOW ROYAL INFIRMARY; LECTURER IN PRACTICE OF MEDICINE, QUEEN MARGARET COLLEGE, UNIVERSITY OF GLASGOW.

II.—A FURTHER NOTE ON COBRA VENOM.

IN a former communication to THE LANCET[1] we described the histological appearances of the central nervous system in six monkeys and three rats paralysed with cobra venom. Since then we have examined in a similar manner the tissues of seven other monkeys and we wish to take this opportunity of putting our results on record. The first four monkeys may be considered as an addition to the series of six already published; but they were also examined with special reference to the action of cobra venom on nerve fibres, especially those in peripheral nerves. The three remaining monkeys were regeneration experiments—that is to say, they were first paralysed by subcutaneous injections of the venom but they subsequently recovered on the administration of an antivenom. The methods of fixing and staining in these seven cases were the same as noted in our former paper except with regard to the peripheral nerves, portions of which were fixed in Müller's fluid and other pieces in perchloride of mercury or formol. The nerves were stained by (1) theoin (for nuclei); (2) hæmatoxylin and benzo-purpurin (for axes cylinders and nuclei); (3) Congo red (for axes cylinders); and (4) Busch's method (for myelin). In the cases in which Busch's method of staining was employed the animals were kept on ice for 24 hours after death before the tissues were removed. The following are the details of the cases :—

---

[1] THE LANCET, Jan. 2nd, 1904, p. 20.

,, ,, 8	2560	0·4	5 ,, 40 ,,
,, ,, 9	9465	0 5	2 ,, 30 ,,
,, ,, 10	2710	0·5	1 ,, 30 ,,
,, ,, 11	3310	0·5	Paralysed in 2 hours 10 minutes; antivenom; recovery in 4½ hours; killed at once.
,, ,, 12	3930	0·5	Paralysed in 2 hours; antivenom; recovery in 6 hours; killed 20 hours later.
,, ,, 13	3210	0·45	Paralysed in 3 hours 40 minutes; antivenom; recovery in 3 hours; killed 44 hours later.

Monkey No. 7, weight 2950 grammes, died in six and a half hours after subcutaneous injection of 0·4 milligramme per kilogramme of cobra venom. Generally the degenerative changes in this case were even more marked than in Monkey No. 1 of our former series. In the cord there were, in the lateral groups of cells, some six to ten cells deeply stained, with chromatic granules still present and fairly consistent, though rather ill defined and lying in a somewhat diffusely stained plasma. The rest of the lateral cells and all the more central cells were devoid of granules and the majority were very pale, indeed typically "ghost" cells. Some few cells showed vacuolation. These degenerative changes seemed rather more marked in the lumbo-sacral than in the cervical region. In the cerebral cortex the appearances were similar to those in the cord, there being a proportion of the larger pyramidal cells deeply stained but with rather ill-defined granulation. The smaller ganglion cells were pale and quite devoid of granules. In the nuclei of the pons and medulla the proportion of almost normal cells was much more considerable. There seemed to be a slight increase of the connective-tissue (neuronophagen) cells throughout the grey matter of the cerebro-spinal system, especially round the smaller and paler ganglion cells. Sometimes these connective-tissue cells were found indenting the margin of the ganglion cell and sometimes even in its interior. With Busch's staining there was no appearance of degenerate fibres in cerebral or cerebellar cortices, or in the pons, medulla, or cord. The anterior and posterior nerve roots were likewise seen to be unaffected. The peripheral nerves examined were the median (near elbow), posterior tibial (portion between soleus and gastrocnemius muscles), and vagus (in cervical region). All of these seemed to show some slight increase of their internodal nuclei but this increase was by no means well marked. With Busch's staining there was no certain evidence of coagulation or breaking up of the myelin. There was some blackening of the fibres in places but this was probably an artefact due, at least in part, to the nerves lying rather long in formol. The axes cylinders were in places slightly swollen but not much more than was to be seen in the control sections; so that this appearance could not be regarded as pathological.

Monkey No. 8, weight 2560 grammes, died in five hours and 40 minutes after subcutaneous injection of 0·4 milligramme per kilogramme of cobra venom. The appearances in this case were much the same as in Monkey No. 7, though not quite so marked and not quite so uniform throughout the whole cerebro-spinal system. For instance, in the lumbo-sacral region of the cord the chromatolysis was just as extensive as Monkey No. 7, while in the cervical cord the number of the almost normal cells lying in the lateral groups was considerably greater. In the pons and medulla, too, excepting the cells of the third nucleus, which had their granules much fragmented, those in the optic nuclei, fifth, seventh, and twelfth were practically normal. With Busch's staining there was no reaction for degenerate fibres in any part of the cortex, pons, medulla, or cord. The appearances in the peripheral nerves were much the same as in Monkey No. 7—namely, slight increase of internodal nuclei with no certain evidence of change in the myelin or axes cylinders.

Monkey No. 9, weight 9485 grammes, received 0·35 milligramme per kilogramme of cobra venom. The day following the animal looked dull but there were no signs of paralysis. Three days later it was apparently quite well and was therefore again given 0·35 milligramme per kilogramme of the venom. It was again dull on the day following but with no [illegible] quite well [illegible] then give[illegible]ours. The microscopic appearances in this monkey were much the same as in Monkey No. 3 of our former series, also dead in two and a half hours after injection of the poison. At some levels of the cord the ganglion cells looked almost normal, while at others there seemed undoubted evidence of an early degenerative change. Taken as a whole, we may say that a definite proportion of the ganglion cells of the lateral groups were too diffusely stained and had their granules somewhat fragmented. Some cells, too, were rather deficient in granules, especially those cells in the more central groups. The ganglion cells in the nuclei of the pons and medulla seemed practically normal. In the cerebral cortex the ganglion cells were again rather diffusely stained with their Nissl bodies slightly broken up. There seemed in this case also some slight increase in the connective-tissue cells, though in the cord, at least, they did not seem so definitely collected round the ganglion cells, and they were not found indenting their edges nor yet in their interiors. With Busch's staining there was no reaction for degenerate fibres in the cortex, pons, medulla, or cord. The nerves showed very slight, if any, increase of nuclei; there was no definite evidence of their axes cylinders or [illegible]

[illegible] 2710 grammes, received subcu[illegible] per kilogramme of cobra venom. At the end of one and a quarter hours paralysis appeared, and a quarter of an hour later was nearly complete. The animal was then killed by being bled to death, having lived one and a half hours after receiving the poison. The appearances throughout the nervous system in this case were practically normal. In the cord the vast majority of the ganglion cells had their Nissl granules quite consistent and well formed, though in some of the cells they were not so regularly arranged in the cell plasma as in the typically healthy cell. Occasionally, too, one found a section in which these granules seem to be rather deficient in number and not too well defined, as if a solvent had been acting on them. The staining also was more intense than is found in the normal (control) specimens. The same applies to the cells of the cerebral cortex—that was, they were almost normal, though a proportion of them had their Nissl granules deficient and not quite well defined. There was no definite increase of the connective-tissue cells in the grey matter of the cerebro-spinal system. The peripheral nerves might be taken as normal, there being no unequivocal increase of their internodal nuclei.

Monkey No. 11, weight 3310 grammes, received subcutaneously 0·5 milligramme per kilogramme of cobra venom. In two hours and ten minutes there were signs of paralysis in the limbs and the breathing was laboured. Antivenomous serum (ten cubic centimetres) was given intravenously. 50 minutes later paralysis was still present—that was, the animal could move about but with its legs dragging along the ground. Antivenomous serum (15 cubic centimetres) was now given subcutaneously. One and a half hours later all signs of paralysis had gone and the animal was then killed by bleeding from the femoral artery. The appearances of the ganglion cells in this case were of some interest, for when compared with the sections from the two following cases (Nos. 12 and 13) there seemed little doubt that there had been some change in the cells from which they had not yet recovered. In the cord quite 50 per cent. of the cells showed some deficiency of Nissl granules and many of them had these granules fragmented, giving a much finer granulation to the plasma than was normal. In some cells the granulation was quite dust-like, but all gradations were found between these and the cells with Nissl bodies of normal size. The proportion of cells affected in this way varied somewhat at different levels but in lower voltage than an animal twice its size. Frequently it was the reverse of this. Circumstances suggested to us that the younger and the less highly organised the animal the higher often was the potential required to kill it when compared with that needed for an older animal.

Prevost and Battelli[7] of Geneva found that alternating currents of feeble tension—e.g., 120 volts—caused fibrillary tremor of the heart and that it was this circumstance which dominated all the other phenomena. The action of the *heart was arrested after contact of one second. Occasionally* there was a generalised tetanus with opisthotonos followed by clonic convulsions. Prevost and Battelli divided electrical currents into high, medium, and low, rather an arbitrary division on the whole. In dogs receiving 240 volts for two seconds the heart presented fibrillary tremor and there was generalised tetanus followed by complete arrest of respiration; with 600 volts for two seconds there was fibrillary tremor of the heart with convulsions but no respiratory movement; while with currents ranging from 240 to 600 volts there was produced in dogs simultaneous arrest of heart and respiration. These observers found (1) that currents of low tension produced paralysis of the heart; (2) that mean tension currents produced simultaneously paralysis of the heart and respiration; and (3) that high-tension currents caused principally nervous symptoms. The particular part of the body at which the electric current enters is of importance. Arrest of breathing and the development of convulsions were induced by a smaller voltage when the electrodes were applied to the head. The mode of death from continuous currents they found to be in the main similar to that brought about by alternating currents; also that currents of 550 volts caused rapid fall of arterial pressure due to paralysis of the heart.

D'Arsonval held the view that the continuous current was only risky to life when the circuit was broken, but most observers while admitting that the shock is more dangerous when the circuit is broken, yet are of opinion that closure of the circuit is equally dangerous. Battelli found that there was no exact relationship between the electrical energy necessary to cause the death of an animal and its weight, yet maintained, contrary to most observers, that young animals are more sensitive to the effects of electricity than those of maturer age.

R. H. Cunningham[8] of New York from his experiments concluded that although during the passage of the electric current there is respiratory standstill, yet the respiratory centre in the medulla is neither paralysed nor instantly killed, otherwise no natural rhythmical respiratory movements could occur after the circuit is broken. He found that the currents affected principally the left wall of the heart. There was cessation of the heart's beat upon closure of the circuit. Currents of from 110 to 120 voltages readily killed dogs when passed for one minute 16 seconds from the head to the thorax. The currents were equally fatal when carried through the thorax by attaching the electrodes to the forearms, or one to the left forearm and the other over the heart. Cunningham found that young, well-nourished, and hardy dogs withstood a slightly greater strength of current through the chest for a longer time than ill-nourished or older dogs and that the minimum strength of current required to stop the heart of different dogs bore no definite ratio to their size and weight. "Besides the influence exerted by the quality, duration, strength, and density of the current there must be some other factor, apparently residing in the heart and probably physiological in nature, which exercises an influence in the readiness with which the cardiac effect is produced." An enfeebled state of health, for example, may increase the susceptibility of an animal to electrical shock. In cases where men have received severe but not lethal shocks there has usually been before consciousness is lost a moment or two during which strange sensations have been experienced, not necessarily of pain but as if the muscles were all drawn and a sensation of tremendous pressure felt across the chest. Owing to the severity of the muscular spasms a man falling upon the live rail might be thrown in one or other direction, thus breaking his connexion with the live contact.

Voltage Required to Kill.

Opinions are divided as to the voltage required to kill. The professor of electrical engineering at University College, London, Dr. J. Ambrose Fleming, tells us that at one time he thought it was only high voltages that killed. This opinion he no longer holds. The peculiar circumstances operating at the time must be taken into consideration. Men may not be killed on brief contact with 2000 volts while contact with 500 may prove fatal. Railways run at from 300 to 600 volts and this is allowed by the Board of Trade in the belief that it is not dangerous. Experience does not confirm this opinion, as contact with lower voltages has shown again and again. In a public bath in London a man recently lost his life by accidentally placing his hands upon the electric light wires in which the pressure was only 250 volts, the same as in private houses. In this case the danger was increased owing to the man's hands being wet. The risks to workmen on the railway are intensified during wet weather. To these men the danger lies in placing one foot on the live rail while the other is on earth. As Professor Fleming says, "You may stand on a live rail or even sit or lie on it. ...... There is no danger so long as you are entirely on the rail. If you could be absolutely insulated from the earth there is probably no pressure of current that would do you any harm. The danger comes when one part of you, especially a bare part such as the hand or face, touches the live rail and some other part is in contact with the earth. That is where the 'live' rail constitutes so grave a danger." With railway lines in the open country the danger is not alone that cattle or sheep may stray upon them, but that the animals may be electrocuted and their bodies falling upon the track may become the cause of an accident to the train that follows. If the lives of the travelling public are to be safeguarded there must be adequate covering of the elevated rail, not only at stations and level crossings, but along the whole length of the track. The manner in which this rail should be protected is a matter for electrical and railway engineers. Gloves made of indiarubber should be worn by men who are proceeding to rescue the victims of electrical shock on a railway, and on carefully removing these unfortunate persons from contact with the elevated rail artificial respiration should be at once resorted to in cases of suspended animation and maintained for a considerable length of time, for more than half an hour if necessary. Cunningham recommends transfusion of defibrinated blood as an accompaniment to artificial respiration. This method of treatment has been followed by good results in his hands but it is evidently more likely to be adopted and to prove more successful in the laboratory than on a railway line for example.

Newcastle-upon-Tyne.

ON THE ACTION OF VENOMS OF DIFFERENT SPECIES OF POISONOUS SNAKES ON THE NERVOUS SYSTEM.

BY GEORGE LAMB, M.D. GLASG.,
CAPTAIN, I.M.S.; ASSISTANT DIRECTOR, PASTEUR INSTITUTE OF INDIA;
AND
WALTER K. HUNTER, M.D., D.SC., F.F.P.S. GLASG.,
ASSISTANT PHYSICIAN, GLASGOW ROYAL INFIRMARY; LECTURER IN PRACTICE OF MEDICINE, QUEEN MARGARET COLLEGE, UNIVERSITY OF GLASGOW.

II.—A FURTHER NOTE ON COBRA VENOM.

IN a former communication to THE LANCET[1] we described the histological appearances of the central nervous system in six monkeys and three rats paralysed with cobra venom. Since then we have examined in a similar manner the tissues of seven other monkeys and we wish to take this opportunity of putting our results on record. The first four monkeys may be considered as an addition to the series of six already published; but they were also examined with special reference to the action of cobra venom on nerve fibres, especially those in peripheral nerves. The three remaining monkeys were regeneration experiments—that is to say, they were first paralysed by subcutaneous injections of the venom but they subsequently recovered on the administration of an antivenom. The methods of fixing and staining in these seven cases were the same as noted in our former paper except with regard to the peripheral nerves,

[8] Cause of Death from Industrial Electric Currents, New York Medical Journal, 1899.

[1] THE LANCET, Jan. 2nd, 1904, p. 20.

20 hours after recovery from paralysis, so that it would seem that regeneration of the ganglion cells takes place sometimes within 20 hours after disappearance of the symptoms of paralysis But we hope at some future time to study more carefully the process of regeneration in the ganglion cells either with cobra venom or with one of the other snake poisons

In concluding, we wish to express our indebtedness to Dr J Lindsay Steven for the use of his laboratory and apparatus in carrying out a part of this investigation One of us (W K H) has also to acknowledge aid from the Carnegie Trust in the form of a grant towards the expenses incurred in this investigation

THE

RESPIRATORY AND CARDIAC REFLEX INDUCED BY PERIPHERAL IMPRESSIONS ON THE PUDIC NERVE DURING ANÆSTHESIA

By ALEXANDER WILSON, F R C S Eng ,
SENIOR ADMINISTRATOR OF ANÆSTHETICS TO THE ROYAL INFIRMARY MANCHESTER SURGEON TO THE MANCHESTER AND SALFORD LOCK HOSPITAL.

IN his "Address in Surgery' to the British Medical Association Sir William Macewen refers to the familiar spasm of the glottis produced during anæsthesia by forcible dilatation of the sphincter ani or irritation of the parts supplied by the pudic nerve In these circumstances this spasm is part, often the only surviving part, of an expulsive effort and has, I think, been recognised as such for some time The causes which give rise to it are of a kind which in normal circumstances tend to initiate expulsive efforts Chief of these are any sudden increase in the intra abdominal pressure—e g , distension of the bladder or rectum, the reduction of large herniæ of old standing, the introduction of the hand or large sponges into the abdominal cavity, dilatation of the sphincter ani and occasionally of the os uteri, &c It may also be produced by any peripheral irritation especially in young subjects Its occurrence in the course of surgical interference comes about in the following manner

Expulsive efforts are performed through the agency of the respiratory and other nerve centres in response to stimuli reaching them from certain organs and conveyed by various nerves, chief of which are the branches of the pudic nerve Irritation of one of these nerves produces an impression on the centre more or less equivalent to its normal stimulus and evokes a reflex response, just as irritation of the optic nerve
gives the sensatio
normal stimuli con
bladder or rectum
tion of the sphinc
result in an expuls
depends upon the degree of narcosis, that is, upon the number of unparalysed nerve centres that are left to carry out the act This becomes evident when the constitution of the nervous system and its mode of reaction towards anæsthetics are considered

The nervous system as a whole is composed of numerous nerve centres or nerve mechanisms which appear and reach their maturity at different periods in the evolution of the race and growth of the individual The highest and most complex of these functions are latest developed and least able to resist disease or depressing conditions This also holds good as regards their response to the action of chloroform and other anæsthetics The continued inhalation of chloroform induces a progressive paralysis of the various nerve centres beginning with the highest most complex and latest acquired functions, and ending with paralysis of the fundamental functions of respiration and circulation What is true of the nervous system as a whole is equally true of its more complicated reflex mechanisms which react to anæsthetics in a similar manner Each reflex mechanism consists of a fundamental and accessory elements, which latter by their cooperation assist in the performance of the reflex without being absolutely essential to it Thus in every such reflex there are associated several nerve centres the coordinate action of which is necessary for the complete development of the reflex Under the influence of deepening anæsthesia these associated accessory centres are the first to be paralysed but the essential factor in the reflex resists longest and is the last to disappear

An expulsive effort is a mixed reflex intimately associated with respiration but requiring for its most effectual performance the assistance of various nerve centres Intrinsically it is an expiration, more or less forcible, necessarily associated *with closure of the glottis This sudden closure* or spasm of the glottis is an essential or fundamental portion of the reflex and constitutes the feature which differentiates it from an ordinary expiration This being so, the act of closing the glottis as a fundamental factor in the reflex, should longest resist the anæsthetic, and this proves to be the case Under the influence of the anæsthetic the associated nerve centres gradually become paralysed, the response to stimuli becoming less and less complete as fewer nerve centres participate in the action Ultimately when the *narcosis has become profound the essential fundamental* portion of the reflex the closure of the glottis alone survives Finally this too may be abolished and then the only response to stimulation is evidenced by an alteration in the respirations through the effect of the stimulus on the unparalysed respiratory centre Under varying degrees of narcosis every variety of expulsive effort may be seen from a complete effort accompanied with closure of the lips alteration of the facial expression, and ' bearing down in slight anæsthesia, to the faintest *laryngeal stertor or mere catch in the breath in deep narcosis* The spasm cannot be safely abolished because it arises from the respiratory centre which strongly resists the action of anæsthetics

When spasm of the glottis arises as the consequence of peripheral irritation its mechanism would appear to be as follows Sudden acute pain in the conscious subject is met by an involuntary deep inspiration, followed by closure of the glottis and fixation of the chest preparatory to an exclamation or other effort What occurs in the conscious subject tends equally to occur in the unconscious or semi conscious individual but a number of centres being paralysed the action is not complete or properly coordinated, hence the stertor As regards the alteration in the pulse there are two factors The procedures inducing the above abortive expulsive efforts are all painful and as such cause a certain amount of shock and so may influence the circulation Further, the circulation is intimately associated with, and in a measure dependent upon the respiratory movements Any modification of these especially such as increase the intrathoracic pressure as do expulsive efforts of necessity alter the pulse and will account for the majority of the cases

It is interesting to note that forcible dilatation of the sphincter ani has been suggested as a remedy in chloroform accidents, the object being to stimulate respiration Of course in the conscious subject an expulsive effort is preceded by a deep inspiration but in a state of narcosis sufficiently profound to induce respiratory paralysis this would not take place It is questionable if at any stage of narcosis other than a very slight one this almost involuntary preliminary inspiration could be elicited by dilatation of the sphincter ani

Manchester

A CASE OF LATENT PORTAL CIRRHOSIS WITH SUDDEN ONSET OF HÆMATEMESIS AND RAPIDLY FATAL TOXÆMIA

By ROBERT M McQUEEN, L R C P Lond ,
M R C S Eng ,
CLINICAL ASSISTANT AT THE VICTORIA HOSPITAL FOR SICK CHILDREN AND THE GROSVENOR HOSPITAL FOR WOMEN AND CHILDREN

The following case is of interest from the great rarity of the concurrence of these conditions the suddenness and rapidity of the symptoms without any prodromal signs in a case of cirrhosis which had been latent for many years, and the post mortem examination revealing a healthy condition of the abdominal viscera.

On April 26th, 1904, I was called to see the patient a stout, healthy man, aged 56 years He had been perfectly well up to the previous day, but now complained of malaise and drowsiness with a feeling of "fulness in the stomach." Examination proved negative; no pain or abdominal tenderness could be made out. The temperature was normal and the pulse was 76 and soft. Simple gastric sedatives were prescribed. On the next morning at 3 A.M. I was called to see him. When I arrived I found that he had vomited about a quart of blood consisting of small recent clots. He was now in a semi-comatose condition and very irritable and resisted any attempts at physical examination. Later in the day a large motion consisting of altered blood was passed and with considerable difficulty the following points were revealed by examination. In the epigastrium a hard tumour was felt of about the size of the closed fist; it was semi-resonant and apparently the surface was smooth, but owing partly to the patient's mental condition and partly to the fatness of the abdominal walls its relation to the liver could not be definitely made out. The edge of the liver was felt in the right flank about two fingers' breadth below the costal margin. There were no prominence of the superficial abdominal veins, no evidence of ascites, and no œdema of the extremities. The patient was not jaundiced, the tongue was clean, and the breath had no characteristic odour. The temperature was 99° F. and the pulse was 84, soft and regular. The arteries were normal. Examination of the thorax was negative. Later he became delirious and finally comatose but recovered consciousness after an intravenous transfusion of a quart of normal saline solution. Urine was freely passed during this period of consciousness. There were no trace of albumin and no reaction with ferric chloride. The specific gravity was 1030. Unfortunately the improvement of his mental condition was only temporary. In about eight hours his pulse rose suddenly to 132 and suspecting the possibility of another hæmorrhage one and a half drachms of adrenalin chloride were administered by the mouth. Within half an hour the pulse had fallen to 96 with decided improvement in his condition. On the next day the patient rapidly lost consciousness again, the pulse remaining at 96. The weakness gradually increased. Six hours before death the temperature rose to 102·6°, four hours later it was 104·2°, and it was maintained at that point when death occurred.

Post-mortem examination.—Rigor mortis was present. There was about an inch of fat on the abdominal walls. There were no enlarged veins and no signs of jaundice. The abdominal cavity was free of fluid. The tumour felt in the epigastrium was found to be the left lobe of the liver which was moderately enlarged. The liver was "hobnailed." The right lobe was of about the normal size and shape. It cut with increased resistance: on section it showed signs of coarse cirrhosis of a multilobular type. The fibrous tissue was in narrow strands and evenly distributed throughout the organ. The gall-bladder was distended with normal bile, but no calculi were present. The spleen was much softer than usual and about double the normal size. There was no evidence of gastritis in the stomach beyond a small amount of mucus on the walls and it was not dilated; petechiæ were found at the cardiac end on the lesser curvature, over an area about two inches by one inch, together with two or three small erosions at the same spot, but no evidence of eroded vessels was found. Only one inch of the œsophagus *was examined; the veins were very prominent.* The kidneys were healthy. It is to be regretted that only a partial post-mortem examination could be made.

The patient, a hypochondriac whose previous medical history was uneventful, had, so far as it could be ascertained, always enjoyed good health and not suffered from any illness. After his death I was able to obtain a history of free indulgence in alcohol for a year or two which, however, was said to have ceased some seven years or more ago. Since then he had been a moderate liver, though there is reason to believe that for about a fortnight before this illness he had drunk to excess and had suffered great mental distress. Three months previously I had examined him thoroughly but could not find any sign of local or general disease. There had at no time been any epistaxis, nausea, or dyspepsia, beyond occasional attacks of flatulence; neither had vomiting occurred and the bowels were always very regular—in fact, up to the onset of his illness there had been no reason to regard him otherwise than as a healthy man with a tendency to corpulence.

The chief interest of this case lies (1) in the conjunction of hæmatemesis and toxæmia, the latter being possibly exaggerated by the hæmatemesis; (2) the latent hepatic condition; and (3) the fulminating quality of the symptoms when they arose, all of which rendered diagnosis extremely difficult. That toxæmia from some cause or other was present appeared probable from the absence of any definite evidence of an organic cerebral lesion, but with the exception of hæmatemesis and what subsequently proved to be enlargement of the liver the signs upon which to base a diagnosis were purely negative. The urine was free from sugar and albumin. The heart and the radial vessels were healthy and there were no signs of renal disease. Probably in this case an acute process had been set up in the liver by the last bout of drinking, and this, together with the decrease in the coagulability of the blood produced by the alcohol, would account for the rapidity and the combination of the symptoms.

As has been pointed out already, the peculiar feature of interest in this case of latent cirrhosis is the sudden and simultaneous appearance of hæmatemesis, which is usually an early symptom, and of toxæmic coma, usually a terminal event in portal cirrhosis. The most satisfactory explanation would appear to be that sudden and complete insufficiency of the liver supervened, probably as the result of recent excessive alcoholism. Gilbert and Carnot,[1] who speak of this condition as "anhépatie," mention among its manifestations "multiple hæmorrhages, delirium, and coma." It is possible that the small erosions in the stomach were due to the toxic action of the alcohol and their existence might account for the occurrence of the extensive local hæmorrhage instead of multiple extravasations. Latent cirrhosis was thought of and that diagnosis was held tentatively. Less difficulty might have been experienced had an alcoholic history been forthcoming earlier, but its absence at that time, together with the rare combination of hæmatemesis and toxæmia, militated against the theory of hepatic cirrhosis and it is owing to this unusual combination that I venture to place this case on record.

I am indebted to Dr. H. D. Rolleston for his kind suggestions.

Cadogan-gardens, S.W.

THE
MEDICAL TREATMENT OF DEEP-SEATED HÆMORRHAGE.

BY FRANCIS HARE, M.D.,

CONSULTING PHYSICIAN TO THE BRISBANE GENERAL HOSPITAL; VISITING PHYSICIAN AT THE DIAMANTINA HOSPITAL FOR CHRONIC DISEASES, BRISBANE; LATE INSPECTOR-GENERAL OF HOSPITALS FOR QUEENSLAND.

IT is generally admitted that most therapeutic advances have originated more or less accidentally in observation—that is, inductively, not deductively. The therapeutic procedure advocated in this paper, should it be accepted as an advance, is one of the exceptions to the above general rule. It was suggested by physiological considerations and only thereafter put to the clinical test.

It may be stated as not open to question that hæmorrhage, whether arterial or capillary, depends essentially upon the *existence of a certain blood pressure* in the bleeding area and that the indication for medical treatment consists in reducing this localised blood pressure. Such we might hope to achieve: (1) by promoting vaso-constriction of the arterioles supplying the bleeding area; or (2) by promoting fall of blood pressure through widespread vaso-dilation in other areas. It is to the first of these methods that attention is commonly directed. In cases where the bleeding area is accessible to local treatment—for example, in certain cases of hæmatemesis—the promotion of localised vaso-constriction, as by ice pills, adrenalin, &c., may be very successful. But frequently the bleeding area is inaccessible to direct local treatment. Then in order to promote localised vaso-constriction we are forced to fall back upon remedies which promote vaso-constriction generally. Until lately ergot was the remedy usually used for this purpose, but now that far more powerful vaso-constrictor adrenalin is coming into general use. As regards ergot, though I have used it conscientiously for many years in cases of inoperable deep-seated hæmorrhage yet I could never assure myself that it was of real advantage except, of course, in uterine hæmorrhage. But the general, as well as the local, action of adrenalin is undoubtedly capable of checking hæmorrhage in some cases: There are, however, at least two serious objections to all remedies which promote general vaso-constriction effectively. On the one hand, unless the general vaso-constriction is adequately compensated by cardiac inhibition the general blood pressure, including the blood pressure of the bleeding area, will rise rapidly; thus the bleeding might continue or even increase. On the other hand, if the general vaso-constriction is adequately compensated by cardiac inhibition serious symptoms depending on brain anæmia are liable to arise; these might conceivably amount to general convulsions. This danger is not, I think, fully appreciated although it is known that in epilepsy the administration of suprarenal extract increases the number of attacks (Pugh[1]).

---

[1] *Les Fonctions Hépatiques*, p. 273.

These considerations led to the determination to try the second method of reducing blood pressure in the bleeding area, namely, by promoting the fall of the general blood pressure through widespread vaso-dilation, and the administration of amyl nitrite by inhalation was the obvious means of fulfilling this indication. This method, it was argued, would be applicable not alone to cases of hæmorrhage from some part of the systemic circulation but to pulmonary hæmorrhage. For, as Schäfer[2] points out, the blood pressure in the pulmonary circulation may be reduced passively "by a fall of pressure in the left auricle due to diminished resistance in the aortic outflow"; and there could be no question that amyl nitrite would diminish resistance in the aortic outflow. The following is a brief account of the first four cases of hæmoptyis treated by inhalation of amyl nitrite.

CASE 1.—The patient, a man, aged 36 years, who suffers from mitral insufficiency, is often attacked on becoming chilled by hæmoptysis: this probably is a response to cutaneous vaso-constriction. The bleeding had never ceased under two days and usually it had persisted for from two to four days. On the last occasion hæmoptysis began at midnight. There was at the time marked coldness of the hands and feet which was not due to anxiety. The inhalation of one capsule of amyl nitrite instantly relieved the vascular spasm of the extremities, and although the expectoration continued to contain traces of blood until the following day it was quite clear that the bleeding into the lung had been instantaneously checked. (Communicated by Mr. O. S. Hawkes.)

CASE 2.—A man, aged 31 years, a phthisical patient in the Diamantina Hospital, with consolidation and softening at the left apex, had hæmoptysis at 4.30 P.M. One capsule of amyl nitrite was immediately given by inhalation, whereupon the bleeding ceased instantaneously. At 6 50 P.M. there was a slight recurrence and $\frac{1}{100}$th of a minim of nitroglycerine was ordered every two hours. Rather profuse hæmoptysis recurred at 12.40 on the following morning but was again stopped instantaneously by amyl nitrite inhalation. Thereafter there was no further recurrence. In this case there can be no doubt that the bleeding ceased *propter*, and not merely *post, hoc*. On both of the occasions on which the inhalation was given the patient was bringing up mouthfuls of blood at regular intervals of about two minutes and on both occasions the mouthful preceding the inhalation was the last of the series.

CASE 3.—A man, aged 34 years, a phthisical patient in the Diamantina Hospital, with excavation of the upper part of both lungs, had had twelve attacks of hæmoptysis in nine years. Each attack had begun insidiously and steadily increased in severity. On no occasion had he ever had a slight attack of hæmoptysis which had passed off or been overcome without laying him up for ten days or a fortnight, and most of his attacks had constituted serious intercurrent illnesses which had left him conspicuously worse than at their onset and from which he did not recover for some weeks. On Jan. 16th, 1904, he began to cough up a little blood unmixed with his ordinary sputa. He was ordered to bed; all food was stopped, and a five-minim capsule of amyl nitrite was administered. The hæmoptysis stopped instantaneously, although streaks of blood permeated his sputa for a few days. During these days a capsule remained on his locker in readiness and he was instructed to use it immediately should the bleeding recur; it was not required, however.

CASE 4.—A phthisical patient in the Jubilee Sanatorium, Dalby, Queensland, had a cavity in the right apex. On Dec. 6th, 1903, hæmoptysis commenced. Over five ounces of blood had been lost when one capsule of amyl nitrite was administered by inhalation. The hæmorrhage ceased instantaneously and completely. On Jan. 30th, 1904, there had been no recurrence. Dr. Andrew Stewart, the visiting physician of the sanatorium, who reports this case, points out that there was no subsequent local congestion or rise of temperature such as usually occurs after hæmoptysis as severe as in this instance.

In the first of the above cases the proximate factor of the hæmoptysis was in all probability a sudden rise of blood pressure in the pulmonary circulation secondary to increased resistance in the aortic outflow dependent on widespread vaso-constriction of the skin from chill; in the remaining three the proximate factor was probably some extension of the tuberculous or septic ulceration, but in all the rationale of the result was identical—namely, the rapid, though indirect, reduction of blood pressure at the bleeding area.

To sum up, five consecutive attacks of hæmoptysis occurring in four patients were all stopped instantaneously by amyl nitrite inhalation. There has not been hitherto an instance of even comparative failure.

Manifestly in hæmoptysis there is in operation one of the most highly vicious circles in pathology—a circle which is largely responsible for the profuseness and continuance of the hæmorrhage. The intra-pulmonary irritation of the effused blood causes cough; each act of coughing, like any other form of sudden exertion, raises the blood pressure; each rise of blood pressure is apt to induce fresh hæmorrhage; and so on, the circle continuing to revolve in many cases until the loss of blood has been sufficient to reduce the blood pressure materially and thus terminate the hæmorrhage. This natural cure of hæmoptysis was at one period in the history of medicine imitated by physicians who resorted to venesection in this emergency—a somewhat expensive, but by no means irrational, imitation. The treatment by amyl nitrite is another imitation, less complete than venesection, but much more economical. The vicious circle is broken through at the same point and by similar means—namely, reduction of the general blood pressure, but the blood is saved instead of being lost. Consequently the procedure may be repeated as often as is necessary.

The point at which the vicious circle is broken through is of the greatest importance. Too often, I feel sure, I have been tempted to operate upon the cough by opiates such as morphine hypodermically. The resulting cessation of cough tends undoubtedly to the cessation of hæmorrhage, but the blood already effused is retained, decomposes inevitably, and not rarely induces septic pneumonia, high temperature, sweating, and prolonged exhausting illness not infrequently ending in death. This is the history of so many cases which seemed under open-air treatment on the road to rapid recovery that I had come to regard hæmoptysis as a grave misfortune. But if amyl nitrite proves efficient as a hæmostatic the hæmoptysis of phthisis will be largely freed from its subsequent as well as its immediate dangers. For the action of the drug is a safeguard against retention: it is the influx of blood to the ulcerated lung tissue, not the efflux from the air passages, which is checked; and the uninterrupted continuance of cough assures the rapid evacuation of blood already effused. In none of the cases detailed above was there, in so far as could be ascertained, any retention of blood; in none of them certainly was there the least subsequent additional rise of temperature or other complication.

Clinically phthisical hæmoptysis is the most important, because the most frequent, of all the medical or inoperable hæmorrhages. But the treatment by amyl nitrite would be even more directly applicable to cases in which the bleeding is from the systemic circulation. In a series of papers entitled "The Mechanism of the Paroxysmal Neuroses," which appeared in the *Australasian Medical Gazette* for July, August, September, and October, 1903, I argued that the most prominent clinical phenomena of migraine, gastralgia, asthma, and allied affections—namely, pain in the first two and dyspnœa in the last named—depend upon vascular distension due to vaso-dilation correlative of widespread vaso-constriction in other areas. (The evidence in support of this thesis is mainly clinical and circumstantial and cannot be even referred to here through lack of space.) Such vascular distension has terminated not very rarely in hæmorrhage. Thus in migraine there have resulted ecchymoses, sometimes extensive, of the face, scalp, conjunctivæ and choroid (Gowers, Tissot, Labarraque), profuse epistaxis (Liveing), and fatal apoplexy (Hilton Fagge); in asthma there has occurred hæmoptysis proportionate to the severity of the dyspnœa (Hyde Salter); and in gastralgia violent hæmatemesis has taken place.[3] Now, in none of these cases is it possible to be sure that the internal vaso-dilation, proximately responsible for the vascular distension and hæmorrhage, is always secondary to, and compensatory of, the widespread vaso-constriction, especially conspicuous in the cutaneous area; it may be that of some cases the converse holds—that the vaso-dilation is primary, the vaso-constriction being secondary and compensatory. But in either case it is certain that the vaso-constriction greatly intensifies the vascular distension in the bleeding area and consequently that a primary indication for treatment consists in the relaxation of the vaso-constriction. Amyl nitrite will undoubtedly effect this relaxation and thus will relieve the vascular distension; that is, the local blood pressure in the bleeding area. The treatment, however, so far as I know, has yet to be tried in these cases, but I can have little doubt of its success, at any rate its partial success.

---

[1] Brain, 1902, p. 501.

[2] Text-book of Physiology, 1900, vol. ii., p. 150.

In the series of papers already referred to it was also argued that the mechanism of the physiological process of menstruation is identical with that of the pathological processes exemplified in migraine, gastralgia, asthma, &c. It was argued that just antecedent to and during menstruation there is an exaggeration of the normal physiological vascular tone or vaso-constriction in wide areas, conspicuously in the cutaneous area, and that such is compensated to some extent, though not fully, by vaso-dilation in the pelvic, more especially the uterine, area. This vascular modification accounts for the physiological increase of blood presssure antecedent to and during menstruation and for the premenstrual and menstrual incidence of the paroxysmal neuroses; it accounts also for the vascular distension of the uterine mucosa and for the eventuating hæmorrhage or menstrual flow. If this view of the mechanism of menstruation is correct, then anything—amyl nitrite inhalation, for example—which tends to cause widespread vaso-dilation, especially vaso-dilation of the surface, would tend to reverse the whole machinery of the menstrual process and would inevitably diminish, if it did not succeed in terminating, the uterine vascular distension and the menstrual flow dependent thereon. Now it is open for any physician to assure himself that amyl nitrite has this power. But I would not suggest that the experiment be made except, perhaps, in very special circumstances; for I have reason to believe that the sudden cessation of the menstrual flow which is liable to result may be fraught with exceedingly distressing, if not dangerous, sequelæ.

While I was deliberating as to the justifiability of testing the influence of amyl nitrite upon the menstrual flow I unwittingly performed the experiment, thus setting at rest any question as to the capacity of the drug to act in some cases in the manner anticipated. I was called in to see a woman, aged 25 years, who was suffering from vaso-motor angina pectoris. Almost immediately after my arrival a paroxysm occurred. I administered a capsule of the nitrite. The result was the instantaneous cessation of the pain, but the attacks continued to recur during the succeeding three or four days. A week later I learned that the patient had been menstruating when I administered the nitrite and that the period had terminated instantaneously. I then obtained the following history. She had suffered from angina on and off for several years. The attacks were especially prone to occur and to be especially severe on the day preceding and on the first day of menstruation. Several physicians had administered amyl nitrite and this invariably gave instant relief. But whenever she had inhaled the drug during menstruation—and she had done so frequently—the invariable result had been the immediate cessation of the flow and the termination of the period. She had made the further important observation that whenever a menstrual anginal seizure was dispersed by the nitrite with concurrent checking of the flow the attacks continued to recur for several days, but whenever the drug was omitted during menstruation the anginal seizures were limited to the day preceding and the first day of menstruation. Menstruation in her case was exceedingly irregular as regards time of onset and she was of opinion that menstrual periods had often been altogether missed through inhalation of amyl nitrite. Considering the frequency of premenstrual attacks in her case this seems not unlikely.

South Brisbane, Queensland.

THE

RIDEAL-WALKER METHOD OF TESTING DISINFECTANTS, WITH SPECIAL REFERENCE TO THE ACTION OF FORMALIN AND CYLLIN ON THE PLAGUE BACILLUS.

By W. J. R. SIMPSON, M.D. ABERD., F.R.C.P. LOND., D.P.H. CANTAB.,
PROFESSOR OF HYGIENE, KING'S COLLEGE, LONDON;
AND
R. T. HEWLETT, M.D., M.R.C.P., D.P.H. LOND.,
PROFESSOR OF GENERAL PATHOLOGY AND BACTERIOLOGY, KING'S COLLEGE, LONDON.

LAST year Mr. Rideal and Mr. Walker[1] described a simple and ingenious method for testing the germicidal action of disinfectants. The method was so devised that a number of tests with different strengths of the substance at stated intervals could be carried out with a minimum of labour and with the least expenditure of time. The method was also especially devised to compare the disinfecting action of different substances, and as a comparison these authors adopted carbolic acid as a standard. They were thus able to obtain a figure which they term "the carbolic acid coefficient," and which is of especial value for comparative purposes. This figure is obtained thus: the particular strength of the disinfectant which will kill in a given time is divided by the strength of carbolic acid which under the same conditions will kill the same microbe in the same time. Thus if a 1 in 80 solution of disinfectant X will destroy the typhoid bacillus in five minutes and the strength of carbolic acid which will act similarly is 1 in 100, the carbolic acid coefficient of X is $\frac{80}{100} = 0{\cdot}8$; if a solution of disinfectant Y of strength 1 in 150 is similarly equal to carbolic acid 1 in 100, the carbolic acid coefficient would be $\frac{150}{100} = 1{\cdot}5$. The cost of disinfecting can thus also be estimated. If disinfectant X costs the same as carbolic acid, the cost of disinfecting with X would be two-tenths more than with carbolic acid; with Y in the same circumstances carbolic acid disinfection would cost half as much again. Briefly, the details of carrying out the method are as follows. A special test-tube rack is made use of. It consists of a lower tier with five holes for five test-tubes and an upper tier with two rows (one behind the other) of 15 holes each and divided by spacing into three groups of five (or tens reckoning both rows). Into the bottom row test-tubes containing five cubic centimetres each of various strengths of the disinfectant and of carbolic acid for comparison are placed and into each are dropped at intervals of half a minute five drops of a broth culture of the organism chosen —e.g., the typhoid bacillus, bacillus coli, or micrococcus pyogenes aureus, &c. Having finished the addition of the culture to the tubes subcultures are made in nutrient broth, the broth tubes having previously been placed in the rack in the upper tier of holes, a loopful being taken from each tube containing the disinfectant and sown into a broth tube at intervals of half a minute. In this way a subculture is made from each tube after intervals of two and a half, five, seven and a half, ten, 12½, and 15 minutes. The inoculated tubes are then incubated; if growth occurs it is assumed that the organism has not been killed, if no growth occurs it is assumed that it has been killed, and the results may be charted on appropriate forms as shown below. Sterile test-tubes are employed for the disinfecting solutions, the dilutions of the disinfectant are made with sterile tap water with sterilised pipettes, and in this way contamination with extraneous microbes is practically excluded.

Smith and Sommerville[2] have tested the method and have found it work well Sommerville[3] also gives the results of further experiments carried out by the method demonstrating its accuracy The bacillus typhosus, together with the bacillus coli communis, form diffuse abundant growths with more or less isolated microbes in broth cultures 24 hours old We thought it desirable to test the method on a microbe which did not form such satisfactory cultures and we chose for this purpose the plague bacillus which, as is well known, in broth gives a flocculent sticky deposit at the bottom of the tube We used as disinfectants formalin, cyllin, and carbolic acid and broth cultures of plague, 48 and 72 hours old, well shaking and mixing before use Our results were disappointing We often obtained no growth at all in the subculture tubes and the experiments were therefore blanks, or we obtained quite erratic results which were useless for the purpose of arriving at the carbolic acid coefficient Investigating the causes of these results we found in the first place that, contrary to our preconceived idea, broth did not form a suitable culture medium for the test cultures Apparently, in our broth at any rate, a *minute* trace of plague does not grow at all freely in this medium and we found that nutrient agar was a much more suitable culture medium, giving results when the broth cultures under the same conditions were blanks Similarly a broth culture of plague even 72 hours old contains relatively few organisms, or these are aggregated into relatively few masses, compared with the broth cultures of typhoid, &c , and the chances therefore of obtaining a culture from the disinfecting solutions, even though the organisms are not destroyed, are small We therefore substituted for broth cultures suspensions of agar cultures, but as is well known there is great difficulty, owing to the stickiness of the growth, of preparing a uniform suspension and we found it necessary to add much larger quantities of the suspension, 0 5 cubic centimetre of a 48 hour agar culture, to the tubes of disinfectant, thereby reducing their strength somewhat This, however, for comparing disinfectants is of small moment as the results are still *comparative*, which is all that is required We also found it necessary to incubate the culture tubes for a much longer time, at least seven days, as after even five or six days a growth sometimes developed in what previously appeared to be a blank tube Having after a considerable amount of labour and the use of some hundreds of tubes of culture media thus cleared the way, we may give some of the results which we have obtained The results are best charted as follows —

Test No 25, June 20th, 1904 —Bacillus Pestis (Laboratory Culture)

Sample	Dilution	Time culture exposed to action of disinfectant—minutes					
		2½	5	7½	10	12½	15
Formalin	1 in 10	*	*	*	*	*	*
,	1 ,, 20	*	*	*	*	*	*
,	1 , 30	x	*	*	*	*	*
Phenol	1 70	*	*	*	*	*	*
,	1 , 80	*	*	*	*	*	*

x = growth * = no growth

Test No 26, June 20th, 1904 —Bacillus Pestis (Laboratory Culture)

Sample	Dilution	Time culture exposed to action of disinfectant—minutes					
		2½	5	7½	10	12½	15
Cyllin	1 in 1500	*	*	*	*	*	*
,	1 2000	*	*	*	*	*	*
	1 , 2,00	*	*	*	*	*	*
	1 3000	*	*	*	*	*	*
Phenol	1 90	*	*	*	*	*	*

In all cases the subcultures were incubated for at least seven days at 37° C These two tests, which were preliminary ones after having arrived at the proper method, yield no result, the disinfectants being used in too great a strength

Test No 29, July 1st, 1904 —Bacillus Pestis (Laboratory Culture)

Sample	Dilution	Time culture exposed to action of disinfectant—minutes.					
		2½	5	7½	10	12½	15
Formalin	1 in 30	x	x	*	*	*	*
,	1 , 40	x	x	x	*	*	*
,,	1 , 50	x	x	x	x	x	*
Phenol	1 , 100	*	*	*	*	*	*

Test No 30, July 1st, 1904 —Bacillus Pestis (Laboratory Culture)

ample	Dilution	Time culture exposed to action of disinfectant—minutes					
		2½	5	7½	10	12½	15
Cyllin	1 in 3500	x	*	*	*	*	*
,,	1 , 4000	x	x	*	*	*	*
Phenol	1 , 100	*	*	*	*	*	*
,	1 110	?	x	*	*	*	*

From these two tests, performed at the same time, we see that 1 in 30 formalin and 1 in 4000 cyllin have the same germicidal action as 1 in 110 carbolic acid[4] The carbolic acid coefficient of formalin would therefore be $\frac{30}{110} = 0\ 27$ and of cyllin $\frac{4000}{110} = 36\ 36$

Test No 34, July 15th, 1904 —Bacillus Pestis (Virulent Culture)

Sample	Dilution	Time culture exposed to action of disinfectant—minutes.					
		2½	5	7½	10	12½	15
Cyllin	1 in 4000	x	x	*	*	*	*
Formalin	1 , 40	x	*	*	*	*	*
Phenol	1 , 110	x	*	*	*	*	*

From this test we may assume that a slightly stronger solution of cyllin—say, 1 in 3500—would have had a germicidal action equal to 1 in 110 carbolic acid The carbolic acid coefficient for formalin works out at $\frac{40}{110} = 0\ 37$ and for cyllin at $\frac{3500}{110} = 31\ 8$

Our conclusions are therefore 1 That the method, while a very simple and accurate one for organisms which form abundant, uniform, diffuse growths in young broth cultures, is not nearly so satisfactory for an organism that forms a scanty, flocculent, coherent growth in broth like the bacilli of plague or anthrax, in which cases a suspension of an agar culture is to be preferred 2 As the result of a large number of tests the carbolic acid coefficient of formalin for the plague bacillus averages 0 3 and that of cyllin averages 34 0

HOSPITAL SATURDAY AT NEWTON ABBOT—£190 were received as a result of the recent Hospital Saturday collections at Newton Abbot (Devon), the amount being much in excess of the total of any previous year

HABITUAL INEBRIATES—At the meeting of the Monmouthshire Discharged Prisoners Aid Society held at Newport Town Hall on July 28th it was reported that five women belonging to Newport had been discharged from the Brentry Homes and in each case within seven days of their discharge they had been reconvicted of drunkenness

A CAUSE OF INTESTINAL OBSTRUCTION AFTER GASTRO-ENTEROSTOMY.

BY H. M. W. GRAY, M.B., C.M. ABERD., F.R.C.S. EDIN.,
SURGEON TO THE ABERDEEN ROYAL INFIRMARY.

THE patient, an unmarried woman, aged 31 years, was seen by me in consultation on the evening of May 15th, 1904. For some months she had suffered from severe "indigestion," intense epigastric pain, radiating to the back, occurring almost immediately after taking food. She had not vomited during this period but had noticed that the stools were very dark on several occasions. On May 14th she became suddenly collapsed and vomited a large quantity of blood. In spite of medical treatment the hæmatemesis was repeated several times, although not to such a large extent. The bowels were opened and the stool contained a large quantity of blood. On the evening of the 15th she became again so collapsed that death was thought to be imminent. She had recovered somewhat before I saw her. Her pulse was very feeble and irregular. It was occasionally as low as 120 but was usually considerably quicker. It was estimated that she had vomited between two and three pints of blood. By percussion of the shifting dulness, limited to the gastric area, it was found that the stomach contained at least a pint of blood. Nothing had been given by the mouth since the onset of the attack. These facts, considered along with the presence of the large quantity of blood in the stool, made the total blood lost amount to probably between four and five pints. It seemed that the bleeding had stopped and it was thought advisable to wait until the morning, as transference to hospital would have had a severe effect on the patient in her perilous condition. Morphine was given hypodermically and a careful watch was set. She passed a fairly good night but early the next morning she again vomited blood and was removed to hospital. On arrival there she vomited a small quantity of fresh blood, so an operation was carried out at once.

Chloroform was administered and three pints of saline solution were slowly infused into a vein at the elbow. The stomach was exposed by a free incision. Blood was seen to be present in a large amount in the stomach and in the whole length of the intestines. Nothing else abnormal about the stomach was detected by inspection or palpation. The blood was squeezed through the pylorus, the stomach was opened posteriorly and its interior was inspected. No ulcer was seen. A posterior retrocolic gastro-enterostomy was performed. Sutures alone were used.

The patient vomited early on the second day after operation. The vomit contained a small amount of "coffee-ground" material and was foul smelling. Five minims of liquid extract of cascara sagrada were given every hour but after three doses she became sick so it was intermitted for 12 hours and then begun again. An enema was given on the evening of the day of operation to clear the rectum; a tarry motion resulted. Every second day thereafter an enema was administered. On the fourth day the stool was free from blood.

About noon on the sixth day she complained of intermittent griping pain in the abdomen. This continued until the evening when it abated somewhat. It was thought probably to be due to flatus, although previously to this a turpentine enema brought away neither flatus nor fæces. A small dose of morphine was given. She was quite comfortable till 3 A.M. on the morning of the seventh day, when the pains began again and increased in severity as the effect of the morphine passed off. Vomiting occurred on two occasions. At 9 A.M. another turpentine enema was given but with no result. The facial expression was now somewhat drawn and anxious. Vomiting continued at intervals but the pains subsided considerably after the enema. The temperature and the pulse were unaffected. The latter had become reduced in frequency from 144 on the day of operation to 100–110.

Intestinal obstruction was diagnosed and immediate operation was advised. This was declined. I prescribed two drachms of magnesium sulphate by the mouth and eight minims of liquor strychninæ hypodermically. The immediate effect of this was to produce severe colicky pain and acquiescence in operation which was carried out at 4 P.M. It was then found that practically the whole of the small intestine had insinuated itself from left to right through the ring formed at the first operation by the peritoneum of the under layer of the mesocolon, that lining the posterior abdominal wall and forming the upper layer of the mesentery, and completed anteriorly by the gastro-jejunal junction. It was easily pulled back and the ring closed by suturing the under layer of the mesocolon to the upper layer of the mesentery to prevent recurrence of the hernia. Strangely enough, there was enormous distension of the colon with gas. It was found to be quite patent down to the rectum. It was accordingly punctured by a trocar and cannula and the gas let out. A silk suture was inserted to close the opening made by the trocar and a piece of omentum was stitched over that. The gastro-jejunal junction was found to be perfect. The patient vomited once during the evening after the operation but thereafter recovery was uninterrupted and she left the hospital on June 13th. She was seen on July 5th, when she looked extraordinarily well. She had suffered no pain, no indigestion, and no vomiting since her dismissal. The stools had been normal. She now made no restrictions in her diet.

I can find no record in the literature on gastro-enterostomy of such a post-operative condition. Moynihan mentions the occurrence in one of his cases of hernia into the lesser peritoneal sac through the opening, made at the operation, in the mesocolon. This, I think, was discovered post mortem. Both these forms of hernia can, of course, be prevented by the insertion of a few sutures. My action in administering drugs to produce increased peristalsis and pain in order to promote acquiescence in operation has been called in question by some of my medical brethren; I have no doubt of its justifiability. Had I left the patient alone and allowed the pains to develop in strength gradually she probably would not have agreed to operation for another 24 hours when her condition would have been much worse. In cases of acute intestinal obstruction there is often a lull in the symptoms after the storm of onset. This lull is too frequently augmented and prolonged by the use of morphine. I have also frequently noted an abatement after an enema has been administered and it was during such a lull that the subject of these remarks refused operation. For some years I have hinted that such a use of intestinal stimulants might be made and that the result would strengthen the diagnosis in cases of suspected intestinal obstruction but I should by no means advocate their use unless in very exceptional cases.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF CONGENITAL ABSENCE OF ONE TIBIA.

BY H. LENNOX MUNRO, M.B., CH.B. EDIN.,
HOUSE SURGEON TO THE ROYAL LANCASTER INFIRMARY.

A CONGENITAL condition of deficiency or total absence of one or more of the bones of the body is not uncommon and in most cases results in the production of great deformity. Total absence of the tibia would appear to be met with very rarely, the radii being the bones which are most frequently wanting. Cases of absent tibia have been recorded by Bland-Sutton in the Transactions of the Pathological Society of London, vol. xliii., p. 124; by Treves in his "System of Surgery"; and by Parker in THE LANCET of May 27th, 1882, p. 870. For permission to publish the present case I am indebted to Mr. A. S. Barling, honorary surgeon to the Royal Lancaster Infirmary. In the cases described by the above observers the condition was associated with other pathological features, as absence of the radii and the presence of supernumerary digits. In this case the patient was a man, aged 27 years, of short stature and slight build, and the other limbs did not present any abnormal features. The appearance of the deformed limb is well seen in Fig. 1 and the actual outline of the bones is shown in the skiagram (Fig. 2). The thigh was wasted, the muscles being poorly developed; the patella was absent and no signs of the tibia could be made out on examination. The inner border of the leg presented a marked concavity directed inwards; the fibula was prominent and much curved. As the limb was allowed to hang down the plantar surface of the foot looked forwards, the hallux pointing outwards. The foot itself was well developed. The skiagram shows [the bones of the tarsus very much crushed together. The man earned his living by street hawking, and although he was unable to wear any form of artificial limb he firmly refused to consent to amputation.

Lancaster.

EYE-STRAIN AS A CAUSE OF HEADACHE.

By S. W. SUTTON, M.D., B.S. LOND.

ATTENTION having been recently drawn to this subject by Mr. Simeon Snell and others I am induced to send a note of a case I have recently seen for the sake of emphasising this point, especially that in spite of their simplicity and frequency the nature of such cases is apt to be overlooked.

I was asked to see a little English girl, aged nine years, whose sole complaint was said to be frequent headache for more than a year which would not yield to treatment. Her father assured me that it was distressing to the whole family to see such a little girl suffering so much from her head. The headaches had always been considered as "due to the liver" but medicines had given no relief. What struck me almost immediately at my first interview and gave me my first clue to the true nature of the case was this: here was a little well-nourished healthy looking girl who complained of [illegible] nd whose eyes were frequ[illegible] of the orbicularis muscle. Carefully avoiding anything like a leading question I asked the child—"Have you any idea what causes your headache?" to which she replied—"It always comes on after lessons and it is always worse on Tuesdays." The idea was at once scouted by the family and the governess said that such simple and short lessons as the child was put to could not possibly cause headache, although it was admitted that she habitually did more lessons on Tuesday than on other days, so I explained that while lessons meant to them "mental effort" to me the term suggested "ocular effort." After the use of atropin I found in each eye hypermetropia of 1·5 D. and prescribed spectacles accordingly, with the happy result that all headache has entirely ceased.

This case suggests one other point which is worth emphasising—viz., that when ordering spectacles we have to prescribe a spectacle-frame as well as certain lenses. I found that this little girl required a frame with the same breadth of bridge that I myself require, her eyes being unusually far apart.

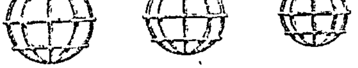
Dharmsala, Punjab.

NOTE ON DR. LANDMAN'S WIRE ARTIFICIAL VITREOUS.

BY JOHN R. ROLSTON, M.R.C.S. ENG., L.R.C.P. EDIN.,

SURGEON TO THE ROYAL EYE INFIRMARY, PLYMOUTH; OPHTHALMIC SURGEON TO THE ROYAL ALBERT HOSPITAL, DEVONPORT.

AMONG the various means which have been introduced for forming an artificial vitreous after excision of an eyeball I think the wire spheres of Dr. Landman of the United States of America deserve recognition. It is claimed for them (1) that they do not require any special instrument for their introduction, as in the case of the smooth glass or metallic spheres; (2) that their retention within the tissues is insured by granulations springing up between the meshes; and (3) that they are very light. They are made in three sizes, as in the illustration, and of pure silver wire. I have used them in about ten suitable cases during the last few months and my experience is that they are very easily inserted, cause little or no irritation, and the after-results as regards movement are very satisfactory. The method I have adopted is after excising the eye to pass a purse suture of catgut around Tenon's capsule, using a plug of lint saturated with adrenalin to arrest hæmorrhage, insert the



wire sphere, and draw the ends of the purse suture together and tie them. I then suture the conjunctiva over the buried sphere. These spheres have been made for me by Messrs. Down Brothers, St. Thomas's-street, Borough.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

MILL-ROAD INFIRMARY, LIVERPOOL.

A CASE OF TROPICAL ABSCESSES OF THE LIVER WITH SOME UNUSUAL COMPLICATIONS.

(Under the care of Dr. NATHAN RAW.)

FOR the notes of the case we are indebted to Dr. Ernest N. Cunliffe, assistant medical officer.

A man, aged 27 years, a discharged soldier, was admitted to the Mill-road Infirmary, Liverpool, on Feb. 17th, 1904, complaining of persistent diarrhœa, severe abdominal pain, and a troublesome cough. He stated that he was in perfect health when he landed in England on Jan. 14th, 1904, after a six years' residence in India. The day of landing he was seized with dull, aching pains in the upper part of his abdomen accompanied by diarrhœa. His bowels were moved eight or nine times daily; he had never noticed any blood or slime in the motions. He did not lie up till a week after the onset of his illness, but he was then obliged to take to his bed on account of the increasing severity of the pains. About this time he first began to be troubled with cough and expectoration; he was quite sure that he had had the diarrhœa a clear week before the cough commenced. On two occasions he had attacks of epistaxis but he had not been troubled with headache or deafness. There had been no rigors but he perspired a little at nights. The diarrhœa, abdominal pains, and cough continued up to admission to hospital. His previous medical history was good. He had never had syphilis, malaria, or dysentery, and he was confident that during his residence in India he had never been troubled with diarrhœa or hæmorrhage from the bowel.

On examination it was evident that the man was acutely ill. He was well nourished and well developed. The face was flushed and the tongue was dry and thinly coated with a greyish fur. The pulse averaged 120 beats per minute and was of low tension but of fair volume. Respirations averaged 30 per minute. His temperature on admission was 101·8° F. Examination of the abdomen showed general distension with pain and tenderness in the right hypochondrium. No rose spots were present. The lower ribs on the right side were unduly prominent and the superficial veins coursing over the right costal margin were distended. The lower edge of the liver was defined as running two inches above the umbilicus. The surface of the liver could not be palpated with certainty on account of the hepatic tenderness but appeared to be of normal contour. The spleen could not be felt. The hepatic dulness extended from the third intercostal space to a level two inches above the umbilicus in the right nipple line. The splenic dulness was not increased in extent. On examination of the chest the cardiac impulse was found to be situated in the sixth intercostal space, two inches outside the nipple line. The cardiac sounds were of good quality with no bruits. On inspection the right side of the chest was more distended and moved less freely than the left. On palpation vocal fremitus was completely absent over the right base and impaired in the interscapular, axillary, and suprascapular regions of the same side; anteriorly and on the left side it was normal. There was dulness to percussion of the right base with impairment of resonance of the right interscapular and suprascapular regions. The right axilla was completely dull. Skodaic resonance was present over the anterior aspect of the right chest as far down as the third intercostal space. The left chest gave a normal note throughout. On auscultation of the right side of the chest breath sounds were absent over the base and diminished in the supra- and interscapular regions. Anteriorly, over the area of Skodaic resonance, puerile breathing was audible. Faint bronchial breathing, bronchophony, and whispering pectoriloquy were heard over the front part of the axilla. Ægophony was nowhere observed. The only adventitious sounds were scanty pleuritic rubs heard anteriorly in the third intercostal space. The auscultatory signs of the left side of the chest were normal. Mensuration showed an increase in girth of three-quarters of an inch of the right side over the left.

An aspirating needle was introduced into the eighth intercostal space on the right side, just outside the angle of the scapula, but only a few drops of blood were obtained, the needle apparently entering solid substance. On introducing the needle a second time about two inches lower down a small quantity of blood-stained pus of a thin consistency was obtained, but free evacuation of the pus could not be obtained. It was decided, therefore, to resort to surgical treatment. The general condition was one of increasing gravity. The diarrhœa still continued, the stools being of a semi-fluid consistency but only on one occasion did they contain shreds of mucus. Blood was never present. The temperature ran an irregular course, alternating between 98° and 102°. The patient was freely stimulated and on Feb. 20th was taken to the theatre and lightly anæsthetised by equal parts of chloroform and ether. Dr. Nathan Raw performed the operation. An exploring syringe was introduced in the right midaxillary line through the ninth intercostal space and a quantity of yellow-coloured pus was withdrawn. The overlying skin was incised and the pleural cavity was opened and about half a pint of sweet-smelling pus was evacuated. Introducing a finger through this opening it was obvious that a localised cavity lying between the diaphragm and the chest wall had been opened. The dome of the diaphragm was evidently pushed up to a considerable extent. A portion of rib was next excised and an opening was made in the diaphragm, when about one and a half pints of darker-coloured pus escaped from a large abscess in the substance of the liver. Examination of the chest showed that the heart had not, however, completely returned to its normal position in spite of the evacuation of such a large quantity of pus and an area of dulness still remained in the axilla. The patient, who up to this point had stood the operation well, now began to show signs of collapse and therefore a large drainage-tube was introduced through the opening in the diaphragm and he was taken back to the ward. He quickly recovered from this temporary collapse and next day his general condition was wonderfully improved. His breathing, though easier, remained somewhat embarrassed and the dulness of the axilla persisted and the cardiac impulse was still located outside the nipple line. He was progressing favourably, when suddenly, on Feb. 22nd, two days after the operation, a profuse discharge of blood, some clotted, some freshly shed, took place from the rectum. A large amount of mucus was mixed with the stool. An enema of starch containing 30 minims of tincture of opium was given and 30 minims of turpentine were administered by the mouth. This treatment checked the hæmorrhage for several hours, but a second attack of bleeding even more severe than the former occurred and though adrenalin hydrochloride was given the patient died from collapse before intravenous injections of normal saline solution could be performed.

Necropsy.—At the post-mortem examination it was found that the lower bowel, especially the cæcum and the colon, was the site of acute dysenteric ulceration, the mucous membrane being acutely inflamed and covered with a thick deposit of blood-stained mucus. The small intestine was healthy. The liver was considerably enlarged and weighed three and three-quarter pounds. In the right lobe were situated two tropical abscesses. The larger one was of about the size of a cocoanut and had been opened at the operation. It was situated on the upper and lateral aspect of the liver and had become adherent to the diaphragm. It still contained a small quantity of rather thick pus, which had not the chocolate colour so characteristic of tropical abscesses but was of a dark yellowish colour. The other abscess was of about the size of a Tangerine orange and was situated just above the gall-bladder on the anterior aspect of the liver and contained pus of similar characters to that found in the larger one. The pus was examined and was found to contain streptococci but no definite amœbæ coli. In the right pleural cavity an interesting condition of affairs was revealed. In its lower part was a small localised empyema, lying between the right dome of the diaphragm and the chest wall and cut off superiorly by dense adhesions from the general pleural cavity. This empyema had been opened at the time of the operation. It had evidently corresponded roughly with the position of the hepatic abscess, being separated from it by the diaphragm. In the upper compartment of the pleural cavity a quantity of perfectly clear, greenish fluid characteristic of serous pleuritic effusions was found. The right lung was floated upwards and forwards, its lower lobe being partially collapsed. The left side of the chest was normal both as regards the lungs and pleura. The heart and other organs were healthy.

Remarks by Dr. CUNLIFFE.—This case presents several features of interest both as regards symptomatology, diagnosis, and complications. It is somewhat unusual for a case of tropical abscesses to run so acute a course. The absence of any history of previous dysenteric trouble is also interesting. When first examined the diagnosis evidently lay between tropical abscess and empyema. The physical signs were consistent with either. The early occurrence of diarrhœa before any chest trouble was observed favoured the former diagnosis. Enteric fever was excluded by the absence of rose spots, enlarged spleen, headache, and by the appearance of the tongue. The termination of the case was unusual, for it is rare for death to take place in dysentery due to sudden profuse hæmorrhage. The most interesting feature, however, is the occurrence on the same side of the chest of [illegible] ic effusion. The right pleural [illegible] ded into two compartments [illegible] between the pleura covering [illegible], and the pleura lining the inside of the chest. In these separate compartments effusion had taken place; in the upper one it was of a serous nature, but the position of the lower compartment separated from the hepatic abscess by the diaphragm had caused the contents of the lower one to be of a purulent nature. The empyema only was tapped at the time of the operation and the presence of the pleuritic effusion in an upper compartment explains the dulness persisting in the axilla and the failure of the heart to return to its normal position. I have ventured to record this case because it illustrates several points of interest occurring in a disease which in this country we have not often the opportunity of observing in an acute form. I am indebted to Dr. Nathan Raw for his kind permission to publish these notes.

PRETORIA HOSPITAL.

A CASE OF ACUTE INTUSSUSCEPTION IN A CHILD FIVE MONTHS OLD; OPERATION; RECOVERY.

(Under the care of Dr. ALFRED W. SANDERS.)

THE patient, a healthy breast-fed male child, was taken suddenly ill about 1 o'clock on Jan. 4th, 1904, and Dr. Sanders was called to see him the same day at 7 P.M. He had attended the mother during her confinement and had not since seen the child but was told that except for occasional slight constipation he had been quite well. The history of the onset was as follows. The child had during the morning been in his usual good health and his bowels had acted naturally. While he was taking the breast he suddenly began to cry as if in pain, turned very pale, and shortly afterwards vomited. He retched and vomited at intervals after this and passed two motions which were rather green and slimy but contained no blood. [illegible] and at [illegible] at 7 o'[illegible] lips. [illegible] The pain was evidently paroxysmal and during the attacks he writhed about and cried pitifully. On examining the abdomen—which was somewhat flattened—a tumour lying above and to the right of the umbilicus was readily detected. The diagnosis of acute intussusception having been made Dr. Sanders advised a consultation and recommended immediate operation. Dr. G. Thornton, a colleague at the hospital, kindly saw the case within a short time and came to the same conclusion. The child was taken at once to the Pretoria Hospital and at 9 P.M. Dr. Sanders operated, Mr. J. S. P. Stewart assisting and Dr. Thornton giving the chloroform. An incision was made just to the right of the middle line and extending one and a half inches above and below the umbilicus. This situation was chosen as being that most likely to give ready access to the tumour with the least exposure and manipulation of the abdominal contents. The intussusception was easily reached and when brought down into the wound was seen to be of the ileo-cæcal variety, the tip of the appendix just presenting at the lower part. Reduction was effected with moderate ease by the invaginated portion being expressed through the sheath. The portions of bowel affected were considerably congested and Dr. Sanders did not think the condition could have been relieved by injections. The wound was closed with silkworm gut sutures passing through all the layers of the abdominal wall. The child stood the operation, which lasted 15 minutes, very well. He was not sick after it and took the breast one hour later. Being restless during the night he was given two one-minim doses of tincture of opium. On the morning following the bowels acted, the motion consisting almost entirely of blood and mucus, and the motions for a day or two were greenish in colour. The recovery was gradual and complete; the temperature ranged between 102° and 103° on the next day but afterwards declined gradually, reaching the normal on the fifth day, while the pulse-rate fell from 144 to 112. The abdomen did not become distended and the bowels acted naturally. No drugs except two one-grain doses of Dover's powder—which were given to induce sleep—were needed. On the 11th the patient was discharged quite well and the stitches were removed on the 16th, the wound having healed completely. A tight binder was worn for some time and now the scar is quite sound. Dr. Sanders was unable to assign any cause for the occurrence of the intussusception.

Reviews and Notices of Books.

Practical Gynæcology: A Comprehensive Text-book for Students and Physicians. By E. E. MONTGOMERY, M.D., Professor of Gynæcology, Jefferson Medical College; Gynæcologist to the Jefferson Medical College and St. Joseph's Hospitals; Consulting Gynæcologist to the Philadelphia Lying-in Charity. With 570 illustrations, nearly all of which have been drawn and engraved specially for this work, for the most part from original sources. Second revised and enlarged edition. London: Rebman, Limited. 1904. 8vo, pp. 900. Price 25s. net.

IN the second edition of this work Dr. Montgomery has carried out an extensive revision of the contents. A large part of the work has been rewritten and its size has been increased by some 70 pages. The author in two new sections discusses the value of the Roentgen rays and the Finsen light in the treatment of gynæcological affections. He comes to the conclusion arrived at by most writers on this subject that so far their application in this branch of medicine is a very limited one indeed; whether in the future it may become more extended remains to be seen. A large number of new figures have been added, replacing in many instances figures which were hardly worthy of the book. In the chapter on Endometritis a series of illustrations representing the microscopical appearances are given and these are a great improvement on the old ones. We notice similar additions in the section on diseases of the tubes and cancer of the uterus. The interesting subject of extra-uterine gestation is very fully discussed and this chapter has been largely rewritten. Primary abdominal fœtation is not accepted by the author as proved and he quotes the case of Tuholske where the placenta was imbedded on the liver as an example of secondary implantation. In cases of advanced extra-uterine gestation where the child is living the author recommends waiting until the eighth month so as to afford the fœtus the best opportunity of being born alive. He considers, as the fœtus may be well developed, that operation should be postponed to such a stage as will give it an opportunity of a continued existence. The statement on p. 637 that the occurrence of fibroid tumours with pregnancy entails a maternal mortality of 50 per cent., and a fœtal loss of 75 per cent. is not quite correct. It would appear as if the author were quoting the results obtained before the introduction of antiseptics. For example, Susserott, writing in 1870 of 147 cases, met with a maternal mortality of 53 per cent. and a fœtal mortality of 66 per cent., while Lefour in 1880 had a maternal mortality in 286 cases quoted by him of 49 per cent. and a fœtal mortality of 77 per cent. Pinard, however, writing in 1901, quotes 84 cases of this complication with a maternal mortality of only 3·6 per cent. and a fœtal mortality of 23·6 per cent.—very different figures to those quoted by Dr. Montgomery and no doubt representing much more accurately the true results of cases of pregnancy and labour complicated by fibroid tumours. In our experience the danger of this condition is often grossly exaggerated in the writings more especially of gynæcologists who are apt to forget the large number of cases seen by the obstetrician which occur with no complications at all. In the section on the operative treatment of fibroid tumours the author has added a description of the various methods of performing the operation of panhysterectomy, and no doubt in this case he is wise, since it is probable that this operation will be considered in the future the best one for dealing with these tumours. The work of revision seems to have been carried out carefully and the book is a fair example of its class, but there is no reason why it should replace the usual text-books with English students.

Studies from the Rockefeller Institute for Medical Research.

Reprints. Vol. I. 1904.

THE Rockefeller Institute for Medical Research was founded in 1901 for the purpose of promoting original research into the causes and treatment of disease. From the introduction to the first volume of studies carried out under the auspices of this liberal endowment we gather that during the years in which the organisation of the institute was being perfected and buildings were being erected the funds have been employed in aiding researches already in progress and encouraging others which seemed promising. In consequence of the grants thus given many workers have been enabled to carry out investigations in various American and European laboratories. The results of 27 of these investigations are recorded but no attention is drawn to what is perhaps the most important aspect of the application of the funds of the institute in this way—viz., the creation of a body of trained workers whose ability has already been put to the test and who will be able to occupy and to turn to account the resources of the laboratories now approaching completion.

The researches recorded have already been published in various periodicals. They cover practically the whole field of experimental medicine. From the standpoint of the practice of medicine five papers on Dysentery are of moment. These seem to leave little room for doubt that acute dysentery, whether sporadic, institutional, or epidemic, in all parts of the world is due to one and the same organism—the bacillus dysenteriæ (Shiga). The results of a study of the acid-resisting group of bacteria have also direct bearing on the practice of medicine and hygiene. As is well known, this group includes also the tubercle bacillus. The authors of the paper hold the designation "bacillus" to be a misnomer and assert that actinomyces would often be the more correct term. Some of the acid-resisting bacteria found in milk, butter, and so on, are capable of causing nodular lesions suggestive of tubercles but distinguishable from them. The majority of these bacteria may be identified from true tubercle bacilli by their inability to resist decolourisation by a 30 per cent. solution of nitric acid in water. We cannot fail to be impressed by the risk of attaching exaggerated significance to so-called specific staining reactions. Much confusion and needless repetition of work would be avoided if the fact is recognised that there is no specific staining reaction either for bacteria or for cellular structures, not even excepting the chromatin elements *par excellence* of the cell.

The papers of highest theoretical promise refer to experimental glycosuria and the new methods which have been applied to the study of this disease. Other researches on cobra venom, bacteriolysis, and agglutination, and various contributions to physiological and pathological chemistry complete a valuable volume of reprints. It is to be hoped that the Rockefeller Institute will fulfil the object of its generous creator and succeed in discovering the investigator who is born, not made, and who only requires proper facilities to enable him to apply his genius to the advancement of medical science and practice.

Text-book of Histology, including the Microscopic Technic.

By Dr. PHILIPP STÖHR, Professor of Anatomy at the University of Würzburg. Translated from the tenth German edition by Dr. EMMA L. BILSTEIN. Edited, with additions, by Dr. ALFRED SCHAPER, Professor of Anatomy at Breslau. With 353 illustrations. London: Rebman, Limited. 1904. 8vo., pp. 485. Price 14*s*.

THE first English Edition of this authoritative work was made from the seventh German edition in 1898. The additions since that date in this translation which has been made from the tenth German edition cover about 60 pages and the increase in the number of illustrations is 61; several of the new illustrations are coloured. The additional chapters deal with the Form of Glands, based on the investigations of Maziarski; the Histological Characters of the Spleen, based on the researches of Weidenreich; of the Urinary Bladder, based on the researches of Lendorf; the Seminal Passages, following the researches of Felix; and the Development of the Hairs, based on the author's researches. The morphology of the cell and the structure and chemistry of the tissues are more fully given than in the previous edition. The technical part of the application of formol and its mixtures is given in some detail. The general arrangement of the chapters is to describe an organ or tissue—as, for example, the kidney, lung, bone, or thymus—reference being made to the illustrations. Directions are then given instructing the student in the mode of hardening or, if need be, of decalcifying, staining, and mounting. The additions are skilfully interpolated and are not unnecessarily prolix. Thus, in the previous edition, speaking of the development of bone and of the origin of marrow, it is merely stated that the primary marrow cavity is a little bay filled with blood-vessels and with cells, the latter in the further progress of development becoming either marrow cells or fat cells or osteoblasts—that is, bone-forming cells. In the new edition the process is more fully and exactly described in the following terms, the description being accompanied by new coloured woodcuts: "The marrow cavity is now a bay-like space filled with blood-vessels and with primary bone marrow, that is with anastomosing branched connective-tissue cells. Some of these cells—the osteoblasts—grow rich in protoplasm and apply themselves in the manner of a one-layered epithelium to the walls of the marrow cavity. These produce bone; meanwhile leucocytes appear in ever-increasing numbers and finally form the chief mass of the cellular elements of bone marrow, therewith converting the primary marrow into the red marrow. Some of the branched connective-tissue cells retain their form and later with a fine fibered connective tissue constitute the supporting framework of the bone marrow. Others of these cells become fat cells." Though Sharpey's name is not mentioned but little, if any, advance appears to have been made in osteogeny since his observations were published. The following gives one of 20 methods of staining preparations and describes von Gieson's method: "Treat sections [of any tissue] with Hansen's hæmatoxylin for 30 minutes. Place the overstained sections in *a*, five cubic centimetres picrofuchsin, 1 3 minutes; *b*, five cubic centimetres distilled water, 10–13 seconds; *c*, five cubic centimetres 90 per cent. alcohol, one minute; *d*, five cubic centimetres absolute alcohol, two minutes; *e*, five cubic centimetres xylol, and when thoroughly cleared *f*, xylol balsam. Result, connective tissue shining red, elastic tissue and muscular fibres yellow, and nuclei brown." Further directions are given to fix the colours. Professor Stöhr's work is a valuable one and may be read with advantage with one or another of the histological text books of home production.

Immune Sera Hæmolysins Cytotoxins and Precipitins. By Professor A. WASSERMANN, M.D. Authorised translation by CHARLES BOLDUAN, M.D. London: Chapman and Hall; New York: John Wiley and Sons. 1904. 12mo, pp. ix.-76. Price 4*s.* 6*d.* net.

IN the preface to this little book the author with characteristic modesty explains that his object is "to introduce my colleagues to the essentials of the subject" and a careful perusal of the 76 small pages of fair sized print will undoubtedly convince the reader that they are admirably adapted to that end. To the busy physician who sees that so much attention is being devoted to the elucidation of problems connected with the constituents of immune sera, no less than to the student just entering on the study of comparative pathology, this work will be very welcome, for in short clear sentences illustrated by well chosen experiments dealing with fundamental facts Professor Wassermann sets out the chief of the elementary data relating to hæmolysins, agglutinins, cytolysins, and so on, and their antibodies whether met with in nature or produced as the result of animal experimentation; he also demonstrates the close family relationship existing between these complex bodies and explains their modes of action and interaction.

Dominated as the whole subject of serum immunity is by that brilliant conception of Ehrlich—the side chain theory of immunity—it is not surprising to find that the author who has himself done much good work on similar lines gives his almost unqualified adherence thereto and employs it with a clearness of diction as pleasant as it is intelligible, to explain the various phenomena associated with hæmolysis and cytolysis. Like Ehrlich Professor Wassermann supports the view of the plurality of complements, interbodies, and the like; and also (p. 24) the theory of the formation of tetanus antitoxin by the cells of the central nervous system, a theory upon which much doubt has been thrown by the recent work of Meyer and Ransome.

Perhaps the most interesting and at the same time the most suggestive section in the book is that dealing with the cytotoxins and their antibodies, for the researches of von Dungern which have resulted in the production of an anti serum capable of destroying the ciliated tracheal epithelium of the ox at once lead to speculation as to whether it is in this direction that we must look for a therapeutic agent in the treatment of epithelial cells of pathological origin. The practical applications too of the precipitins are also touched upon and the author gives a short account of his method of differentiating albumins, laying particular stress on its value to the medical jurist in differentiating the blood of man and closely allied apes from that of other mammals, and to the food inspector in detecting the substitution of horse flesh for beef. To the translator we would offer our congratulations on the manner in which he has presented Professor Wassermann's lectures to the English reader; at the same time we wish he could have seen his way to adding an index as well as the very complete table of contents.

Atlas of the External Diseases of the Eye. By Professor Dr. O. HAAB of Zurich. Authorised translation from the German, edited by G. E. DE SCHWEINITZ, A.M., M.D., Professor of Ophthalmology in the University of Pennsylvania, U.S.A. With 98 coloured lithographic illustrations on 48 plates. Second edition. London, Philadelphia, and New York: W. B. Saunders and Co. 1903. Crown 8vo. Price 13*s.* net.

THIS work is a translation of one of the hand atlases of Professor O. Haab and is a companion volume to his "Ophthalmoscopy" which we had recently occasion to review in these columns. That work was devoted to the representation of the internal diseases of the eye as seen with the ophthalmoscope; the present one deals with the external diseases of that organ and will probably prove more generally useful and attractive. The general practitioner, if unfamiliar with the ophthalmoscope or indisposed to rely upon his own diagnosis of the internal affections of the eye, such as optic neuritis, optic atrophy, or choroidal trouble, may, without derogating from his position as a man of sound information, recommend a patient with failing vision to apply to an expert, but such patient would call his general knowledge in question were he unable to recognise and to treat an external disease which is obvious to the most casual observer. The plates before us enable him to do this with ease. There are few of the commoner affections of the eye and its appendages, except perhaps, nævus, which are not here represented, and generally speaking with great care and fidelity to nature. They have been executed at the lithographic institute of Reichhold of Munich from drawings made by Mr. J. Fink, and they are so true that it is not difficult to name them without reference to the legend on the opposite page. Amongst the best are those exhibiting the various forms of conjunctivitis which accompany or follow gonorrhœa, diphtheria, and other infectious diseases. The text, which extends over 280 pages, is a running commentary on the drawings with, of course, explanations of the appearances they present. It contains a good section entitled Detection of Malingerers. Simulated amblyopia is admittedly a very difficult problem to solve if the supposed impairment of vision is only slight and the deceiver be careful to avoid exaggeration in his statements or if he knows something of the tests to which he will be subjected. Probably the employment of prisms scientifically applied is the most effective method of exposing the cheat. Much credit is due to Messrs. Saunders for presenting to the profession an English translation of so useful a book.

LIBRARY TABLE

The Care and Feeding of Children. By L. EMMETT HOLT, M.D. With an Introduction by ERIC PRITCHARD, M.D. Third edition. London: Sydney Appleton. 1904. Pp. 150. Price 2*s.* net.—Dr. Holt is so well known as one among the first authorities upon the diseases of children, their care, their feeding, and their upbringing that it seems superfluous to praise the little book now before us. Its sub-title is "A Catechism for the Use of Mothers and Children's Nurses," and this admirably describes the scope and aim of the work. It is written in simple language and nearly every imaginable point that can raise a doubt in the mind of one having the care of a child appears to be discussed. The English reader may be reminded that the word "rare," p. 112, as applied to meat does not mean "uncommon" but simply "underdone." The section on feeding is altogether admirable and the whole book can be strongly recommended to those for whom it is written and to many young practitioners as well.

Murray's Handbook for Switzerland. Nineteenth edition. London: Edward Stanford. 1904. Pp. cvi.—555. Price 10*s.*—Murray's Handbook to Switzerland was first published 66 years ago and the present, the nineteenth edition, has been thoroughly remodelled and revised. These extensive alterations have been necessitated by the great changes which have occurred within the last few years in Swiss methods of travel, such as the opening of many mountain railways. No one, of course, can really test the excellence or otherwise of a guide-book without going to the places mentioned therein but the name of Murray is a guarantee for goodness in a guide-book and this tradition loses nothing by the publishing having been transferred to the house of Stanford. The book is full of information which is very clearly set out and the instructions to travellers at the beginning are very good and greatly enhanced by the presence of 34 maps and plans.

Devices and Desires. By P. H. Lulham, M.R.C.S., L.R.C.P. London: R. Brimley Johnson. 1904. Pp. 211. Price 3*s.* 6*d.* net.—Mr. Lulham's verse is graceful and musical if not of a very high order and his ear but seldom fails him. But he has the faculty of painting landscapes in words, as in "November," "Red Dawn," and "A Winter Morning." We must say that we envy Mr. Lulham's poetic fancy which enables him to visualise such a charming rural scene as he gives us from the rattle of a milk-cart heard in the early morning. But we take it that he does not live in London. "Loss" is worthy to be set to music and the "Christmas Hymn" breathes the true spirit of Christmas.

JOURNALS AND MAGAZINES.

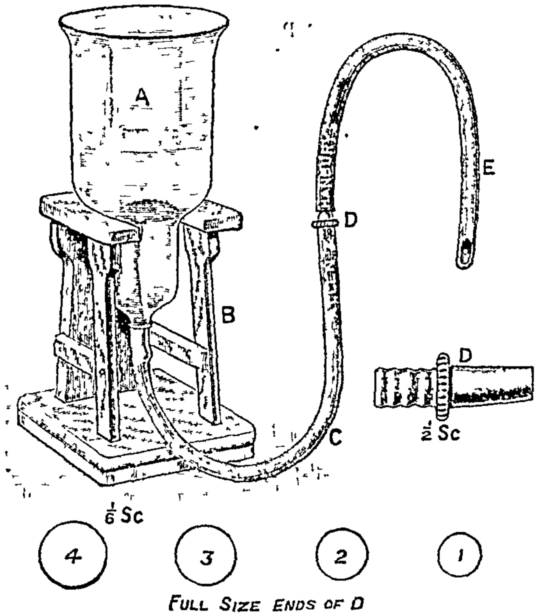
The Quarterly Journal of Microscopical Science. Edited by E. Ray Lankester, F.R.S., assisted by Adam Sedgwick, F.R.S., W. F. R. Weldon, F.R.S., and Sydney J. Hickson, F.R.S. With lithographic plates. London: J. and A. Churchill. Vol. 48, Part I., July, 1904. Price 10*s.*—The articles contained in this number are: 1. On the Branchial Vessels of Sternaspis, by Edwin S. Goodrich, M.A. This is a careful description of the branchial vessels of this chætopod, adding to and correcting the statements of Rietsch and of Vejdovsky, with two plates. 2. The Middle Ear and Columella of Birds, by Geoffrey Smith, B.A., with seven figures in the text. 3. Notes on Rhabdopleura Normani, Allman, with a plate. 4. Some Observations on the Anatomy and Affinities of the Trochidæ, by W. B. Randles, B.Sc. Lond. The anatomy of this group of molluscs is given in full detail and there is a good bibliography. 5. The Anatomy of Pœcilochætus, Claparède, by E. J. Allen, D.Sc., with six plates and one figure in the text. This is an important memoir very well illustrated. 6. Notes on Sporozoa, by H. M. Woodcock, B.Sc. Lond. The author of this article gives the results of his examination of Klossiella muris, a new genus and species of Coccidiæ found parasitic in the kidneys of the mouse. It is extremely small.

The *St. Bartholomew's Hospital Journal* of July 15th is a special number devoted entirely to the recent laying of the foundation-stone of the new buildings by His Majesty the King. A full account of the proceedings at the ceremony is given together with numerous illustrations and altogether the number forms a fitting memento of an auspicious occasion.

New Inventions.

AN IMPROVED APPARATUS FOR AUTO-LAVAGE OF THE STOMACH.

In cases where regular washing of the stomach is necessary the operation will in most instances eventually devolve upon the patient himself and it becomes of the greatest importance to provide him with an apparatus which will make it as easy for him as possible. The disadvantages of the ordinary funnel set of apparatus have been pointed out by me elsewhere.[1] The funnel with narrow thick-walled stem and the glass connecting piece, which cannot be easily detached during use, import needless and gratuitous difficulties, but by a little modification and the addition of a stand in which the funnel can be placed, an arrangement can be assembled which can be used single-handed with great ease. There are several little points which are not usually troubled about by instrument makers but which make all the difference between a practicable and an impracticable device. In the first place, at no point must the calibre of the channel through which the contents of the stomach pass be less than that of the stomach tube. This is obvious, as otherwise one loses all the advantage of a larger tube. In the apparatus usually supplied by the shops there are two points which are narrower than the calibre of the stomach tube—i.e., the neck of the funnel and the glass connecting piece between the stomach tube and the rest of the apparatus. Secondly, it is often necessary to disconnect the stomach tube during the act of lavage to blow down it and to dislodge impacted fragments of food. This is impossible when the connexion is a piece of glass tubing often wired on. In the apparatus which I have devised and which my patients have now used for some time I have attempted to remove these disabilities and, I hope, with success. The apparatus consists of a funnel (A) of such a shape that it will sit easily upon the stand (B). The stem has a bore larger than that of the largest stomach tube and the use of a rubber tube (C) of such a size that it will fit easily over it is rendered possible by the large size of the proximal end of the connecting piece (D). The connecting piece (D) is furnished with a conical extremity to fit into the stomach tube, the end being sharp, and thus presenting no obstruction to the flow through it. In fact, if a connecting piece be selected the end of which is a trifle larger than the calibre of the stomach tube there will be an uninterrupted passage of the same size from the eye of the stomach tube right up to the funnel. These connecting pieces are made in four sizes, shown at (1), (2), (3), and (4). The most important novelty about the apparatus



Full Size Ends of D

---

[1] Manual of Intra-gastric Technique, p. 87.

is the weighted stand in which the funnel is placed whilst *pouring the water into it Both hands of the patient are left* at liberty and he is enabled to go through the operation of lavage unaided without the least difficulty The use of the stand will also be found of great assistance by the physician when washing out the stomach and no one who has once experienced the convenience of it will readily revert afterwards to the old method The apparatus is manufactured by Messrs Allen and Hanburys

Harley street, W GEORGE HERSCHELL, M D Lond

A NEW INHALER

Messrs Down Brothers have constructed for me a modification of Dr J F W Silk's excellent metal inhaler for A C E mixture which should prove a convenience to practitioners desiring to have the facility for administering any of the usual anæsthetics without carrying a separate inhaler for each As so modified the inhaler may be used for chloroform, mixtures of chloroform and ether ether, ethyl chloride or nitrous oxide The chief alterations and additions which I have made in Dr Silk's model are as follows

1 For use with chloroform (*a*) A tap inserted at the nasal side of the inhaler permits the metal part to be used as the face piece of a Junker's inhaler by attaching the tubing of the bellows to the tap, and I have had the holes of the lid enlarged so as to allow a total of more than a square inch of air way through the lid (*b*) If it be preferred instead to administer chloroform or mixtures of chloroform and ether by the drop method then the lid being opened a piece of lint can be introduced and pressed down to the drip diaphragm" (instead of the sponge, as in Dr Silk's instrument) by means of an expanding spring-clip (*vide* Fig 1).

FIG 1

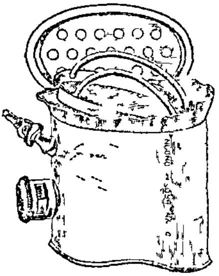


FIG 2

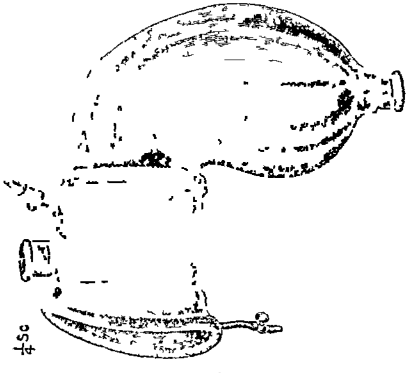

2 For use with ether a detachable rubber cushion face piece and *detachable* d by withdrawing the lint and instead a sponge and attaching piece (as in Fig 2) an inhaler inhaler is produced, with the same advantages of wide bore and ease of respiration The whole apparatus can be easily sterilised by boiling except of course the sponge

3 With the apparatus thus arranged as a closed inhaler ethyl chloride may be administered alone or as a preliminary to ether by spraying it upon the sponge

4 If it be desired to use the inhaler for nitrous oxide alone the sponge or lint is withdrawn and the rubber face piece and bag are attached The expiratory valve on the face piece is opened and rubber tube conducting the gas is connected with the stopcock on the face piece If desired air may be admitted by opening the slot in the distal end of the bag Respiration is particularly quiet and easy with this inhaler under nitrous oxide and I have also found it to work satisfactorily with any of the anæsthetics mentioned

MEETING AT OXFORD

THE SECTIONS.

OBSTETRICS AND GYNÆCOLOGY

FRIDAY JULY 29TH

THE acting President Sir ALAN REEVE MANBY (East Rudham) called upon Dr A W ADDINSELL (London) to read his paper entitled

A Further Contribution towards the Study of the Natural History of Tubal Gestation

Dr Addinsell reviewed the conditions bearing on the treatment of cases of tubal gestation, tubal abortion, and rupture in tubal gestation He gave a careful description and classification of the clinical symptoms diagnosis, and the various indications for operative and expectant treatment according to the circumstances of each case The main contention of the paper went to show that often the pathological results and conditions following on tubal abortion and rupture especially in the earlier months tended to clear up and the patients to recover without the need for any surgical interference He quoted cases illustrating his contention and ended an instructive and interesting paper with a complete and exhaustive list of the various phases and clinical conditions of cases in which an expectant line of treatment was called for and those cases in which operative interference was either immediately or remotely necessary

Dr C E PURSLOW (Birmingham) discussed the difficulties of diagnosis and the indications for and against operation and quoted an illustrative case in which ectopic gestation with its consequences were found on operation although the case was one in which a diagnosis of ruptured gastric ulcer had previously been made

Dr E T DAVIES (Liverpool) thought that the main difficulties of deciding whether operation was called for or not rested on a diagnosis of not only the nature of the case but its exact conditions from time to time Many cases undoubtedly recovered without any operation Nevertheless owing to the liability to subsequent trouble in the pelvis he thought that operation should be carried out in the first place

Dr J INGLIS PARSONS (London) thought that no definite statement could be made on the subject of any value unless details of 100 cases of those operated on at the time of onset and of those which had been left to recover spontaneously respectively were carefully prepared and tabulated Speaking from his own experience and judging from the unsatisfactory after results of cases which had spontaneously recovered he was decidedly of opinion that operation in all cases should be the routine if there was a doubt

Dr ADDINSELL replied supporting his contention of non operative treatment in suitable cases

A discussion then took place on

The so called Ovarian Pain, its Causes and Treatment

Dr G E HERMAN (London) opened this discussion by a crisp, short, and well-arranged paper. He indicated the seat of so-called ovarian pain as corresponding to a point two inches internal to the anterior superior iliac spine in the area of the distribution of the tenth dorsal nerve to the abdominal wall. Pain at this spot was elicited on deep pressure and it was therefore thought that the pain was due to pressure on the ovary. He did not think that the pain was really ovarian. He divided the subject into three—the pain, its nature and causes, and its treatment. The so-called "ovarian" pain might be one of four kinds. 1. Peritoneal pain—outside the scope of the discussion. 2. Reflected pain from visceral disease. Reflected pain might be caused by disease of the subjacent ovary; if so, what was the disease? This kind of pain might also, however, be the result of disease of the bowel, the liver, the gall-bladder, the kidney, the ureter, or the Fallopian tube. When produced by disease of the ovary it was pain and tenderness of the skin and not of the ovary. Other causes not associated with signs of disease might bring about this pain. Two conditions of the ovary had been said to cause chronic pain: (*a*) sclero-cystic disease; and (*b*) cirrhosis of the ovary. Ovarian cystic disease was usually painless. The second was due to changes in the ovary no more painful than was the same condition in the lung, liver, or kidney. The fibrous after-stage of chronic inflammation of the ovary was not painful. Shrunken ovaries were not painful. There was, therefore, no reason why fibrosis of the ovaries should cause pain. Their knowledge of the pathlogy of ovarian atrophy was not very exact. He knew of no way of distinguishing between the various conditions which really caused the so-called "ovarian" pain. 3. Neurasthenic pain. When the resistance of the higher nervous centres was weakened from any cause, pain might become aggravated and extended or it might be manifested without existing disease. Among the weakening causes were: (*a*) anæmia, (*b*) cachexia, (*c*) fever, and (*d*) menstruation. The neurasthenic cause of pain was the most frequent to come under the notice of the gynæcologist. 4. Hysterical pain. This kind of pain did not confine itself to anatomical boundaries, and other signs of hysteria were usually present. The treatment of so-called chronic ovarian pain rested on the removal of its cause, which was often other than the state of the ovary, or depended on neurasthenia or was a manifestation of hysteria. He quoted many cases to show the futility of operative treatment of so-called ovarian pain and laid stress on the return of the pain soon after removal of the ovaries, igni-puncture, resection, or simple removal of cysts. The neurasthenic condition, he recommended, should be treated by tonics, rest, food and sleep, and cessation from a mode of life and surroundings which were conducive to a return of the neurasthenia, and the hysterical pain by suggestion and moral treatment, which must be kept up or the cases would tend to relapse. Operations often acted suggestively to the hysterical patient and so did only temporary good and therefore were not desirable. The reflected pain called for treatment by attention to the evidences of the existence of substantive disease such as erosions of the cervix, uterine conditions, disease affecting the ovaries, tubal conditions, inflammations, adhesions, and the like. He strongly deprecated opening the abdomen for ovarian pain purely, or the removal of the ovaries for pain without strong evidence that the pain was due to actual disease remediable by abdominal section apart from the neuralgic condition of the ovaries.

Mr. F. B. JESSETT (London) said that in certain cases of pain complained of on the right side of the abdomen in the region of the tenth dorsal nerve distribution it was very difficult to distinguish between that referable to so-called ovarian pain and that due to chronic appendicitis. In the treatment of ovarian pain correct diagnosis of the real cause of pain in the locality was the very essence of the matter. He did not agree that there was no pain in sclero-cystic disease of the ovaries; the pain, indeed, was often acute, and if the ovary was removed the pain would disappear permanently. In many cases of cystic disease incision of the ovary and removal of the cyst were all that was necessary.

Dr. JOHN CAMPBELL (Belfast) thought that varicocele of the broad ligament ought to be considered as a cause of the so-called ovarian pain. Chronic constipation was also a cause of the pain and also tended to produce varix of the veins of the broad ligament, just as in the male constipation assisted to produce varix of the veins of the cord.

Dr. HERBERT SNOW (London) said that for the most part he entirely agreed with Dr. Herman's contentions. Constipation was often a cause of so-called ovarian pain. He did not think that hysteria and neurasthenia ought to be considered separately as a cause of ovarian pain. He also thought that irritable endo-cervicitis was often the cause of ovarian pain.

Mrs. F. N. STANLEY BOYD, M.D. (London), said that it was well known that the variability of pain in pelvic organs was common and would account for much of the diversity of opinion entertained by members of the profession. She thought that varix of the broad ligament was possibly a cause of pain, especially in nurses and those who had to do much standing about, as female shop assistants. When it was said that ovarian pain was not due to fibro-cystic disease peritoneal adhesions must be excluded as undoubtedly they were the cause of much pain in some cases. In spite of what was said against operation for pain there were cases which were much benefited by operation and others by general improvement of health following on change of air and tonics.

Dr. EWEN J. MACLEAN (Cardiff) wanted to know how the differentiation of the various conditions was arrived at, for in his experience the matter was no easy one, as must be freely acknowledged by all present. He did not think that the removal of ovaries for ovarian pain would in the future be so frequently resorted to, if at all. Resection was now more usual than removal of the ovaries. He thought, however, that resection was often as great a failure as removal of the ovaries. In his experience neurasthenic cases were just those in which the ovarian pain was most acute.

Dr. HEYWOOD SMITH (London) also discussed the relative merits of operative and non-operative measures and laid stress upon the regions of the abdominal wall in which the reflected pain was manifested.

Dr. CUTHBERT H. J. LOCKYER (London) said that he had examined undoubtedly painful ovaries which had been removed but found no microscopical or pathological change which could be assigned as the cause of pain and the organs were evidently functionally useful. Visceral pain was more marked on the left than on the right side of the body, perhaps because there was some constitutional weakness on the left. Frequent child-bearing and hyperlactation were a fruitful cause of ovarian pain and he quoted a series of cases to show that the ovarian pain was invariably in the left tenth dorsal nerve area on the abdominal wall. He thought that practical medicinal treatment was the correct line and not the operative method.

Dr. INGLIS PARSONS thought that ovarian pain *quâ* pain had really no practical diagnostic value as regards operative or non-operative treatment. The pain in neurasthenic cases was often rheumatic in nature. The ovary was more often not the cause of the so-called ovarian pain. He was of the opinion that in some cases sclero-cystic disease was the cause of pain and quoted a case which had gone from consultant to consultant where he removed a small hard fibroid ovary and cured the pain complained of.

Dr. A. F. H. RABAGLIATI (Bradford) contributed an interesting and valuable item to the discussion in the form of photographs of the variable seats in the body of pain in certain women the subject of ovarian pain. He also showed a series of plates illustrating the exercises necessary for the alleviation of this condition. He contended that the rheumatic and gouty diathesis was commonly the cause of ovarian pain. The condition was really in the nature of a gouty or rheumatic effusion into the stroma of the ovary, just as it was elsewhere in the body. He did not believe in operative procedures, as the disease was in the connective tissues all over the body. The Weir-Mitchell treatment was most useful in many cases, and also regimen in diet, aimed at the aforementioned causes, would be found most useful.

Dr. W. E. FOTHERGILL (Manchester) said that ovulation and ovarian pain were closely connected, as one or other ovary from month to month was usually the site of pain and the painful condition was usually attended with enlargement.

Dr. J. B. HELLIER (Leeds) advocated examination under an anæsthetic in cases of so-called ovarian pain. The main object to be aimed at was to try to cure the pain without operative measures if possible. Those cases in which the ovaries were removed for pain and in which the ovaries showed no evidence of disease were always disappointing in their after-results in every way.

Professor J. W. BYERS considered that the matter resolved itself into three great questions: 1. Was there a cause in the ovary itself to account for the pain? 2. Was pain apart from disease a reason for opening the abdomen?—No. 3. If everything else failed ought the abdomen to be opened? That depended on circumstances very wide in scope. The best treatment was to improve the patient's morale and general health. He could not agree that varix of the broad ligament was a cause of pain, for in those cases in which the condition was operated on no cure had resulted.

Dr. F. W. **FORBES-ROSS** (London) said that as regards the seat of the so-called ovarian pain in the distribution of the tenth dorsal nerve on the abdominal wall he had observed that in affections of abdominal organs which were entirely covered with peritoneum reflected pain in disease was usually referred to the areas round about the umbilicus; on the other hand, where the organ was not entirely covered by peritoneum and some of its surface was in relation to the areolar tissue of the abdominal parietes the pain was usually referred to the locality of the abdominal wall immediately over the organ affected. If the ovary was regarded as an entirely peritoneal-covered organ then the area of the tenth dorsal nerve was properly the ovarian area and this tended to indicate the part played by peritoneal adhesions and sclerosis of the capsule of the ovary in causing pain reflected to the tenth dorsal segment. Often, however, the so-called chronic ovarian painful area was merged into the distribution of the eleventh dorsal nerve on the anterior surface of the abdomen, immediately above Poupart's ligament and around the opening of the external abdominal ring. This was well illustrated in such affections as pelvic cellulitis and conditions referable to the cervix and body of the uterus, for in these affections the area of the eleventh dorsal nerve was always the seat of pain. Attention to this would serve for correct estimation as to the origin of pain which was often not fundamentally ovarian. This was also often combined with pain in the tenth dorsal area and was often sympathetic in the ovarian region with a cause existing in the cervix and uterus. Dr. Herman had mentioned the need of attending to cervical erosions and Dr. Herbert Snow had remarked on endocervicitis as a cause of ovarian pain. He would add to the above the overdistended Nabothian cystic follicle, so frequently present and so often lightly regarded and neglected by the practitioner. Experience had taught him that in many cases without erosion of the cervix but with the existence of one or two Nabothian cysts either in the canal or eccentrically placed on the vaginal surface of the cervix chronic pain in the tenth and eleventh dorsal segment often existed and that on puncture of the cyst with a scalpel, which was painless and did not require an anæsthetic, the pain was removed, along with the frequent [illegible] was glad to hear [illegible] matic and gouty [illegible] lusions. In this connexion he would point out the great efficacy of iodide of potassium in 15-grain doses, repeated twice or thrice. He could not agree that varicocele of the broad ligament was the cause of ovarian pain.

Dr. F. **EDGE** (Wolverhampton) thought that there were many cases where operation for ovarian pain did good service.

Sir A. V. **MACAN** (Dublin) said that he disapproved of the term "ovarian pain." Many cases were mental and impressional in nature. Many women returning from America to Ireland went about from specialist to specialist, knew all about their supposed ailments, and often demanded operation. He did not think it was possible to remove ovarian cystic disease by merely incising one cyst, for the whole ovary was microscopically cystic in many cases. He did not believe that removal of the ovaries for pain *per se* was of the slightest use or could be honestly advocated.

Dr. **HERMAN** in his reply stated that he had addressed the section on so-called *chronic* ovarian pain and not on acute painful conditions of the ovaries, which did not enter into the scope of the discussion. The eleventh dorsal nerve area on the abdomen was of course the area corresponding to the cervix, uterus, and Fallopian tubes; the tenth dorsal nerve area was that appertaining to the ovary and its diseases. He did not think that varix of the broad ligament was the cause of pain, and Mr. A. Pearce Gould had shown in his work on Varix that the pain was the reason for drawing attention to a long-existent varicocele, that varix often existed without pain, and that after removal of the varicocele the pain did not at any rate immediately depart, so that it appeared as if other causes were at work than the mere existence of the varix. Cystic ovaries were removed because they were cystic, and ovaries were removed in painful dysmenorrhœa and not because there was pain only.

Dr. **HELLIER** read an interesting account of a case in which an ovarian tumour was simulated by lymphangeioma [illegible] the tumour removed, [illegible] is. [illegible] tive and well-thought-out paper entitled "Some Cases of Ectopic Gestation."

PSYCHOLOGICAL MEDICINE.

THURSDAY, JULY 28TH.

Dr. J. **BEARD** (Edinburgh) read a paper on

Heredity as Viewed from the Biological Aspect.

The phenomena of [illegible] ited to the germ cells of plant [illegible] germinal in nature. In the proc [illegible] to generation of plants and [illegible] redity were limited to the line of germ cells of each individual, the plant or animal body being regarded as a mere lateral and terminal offshoot of this line. In this sense the parent could not transmit anything to his so-called offspring. "The germ cells were the Alpha and Omega: they passed from a beginning of which we have no knowledge, to an end, which we cannot conceive." Whatever modification the parent may have acquired during its life did not concern or affect the germ cell and hence such modification could not be transmitted to the offspring which arose from the germ cell. "Acquired characters" were thus not transmitted. Dr. Beard then referred to the cutting off of the tails of adult mice which had no effect on the offspring. For though generations of mice might thus be treated, yet the young were always born with normal tails. The recapitulation theory of biologists, according to which every animal in the course of its development "climbed its own genealogical tree," was merely an illusion of the imagination without any basis in fact. The formation of the "embryo" as ordinarily understood was a mere incident in a chain of events. The process of sexual conjugation of a germ cell and a sperm cell was the "loose joining together without blending of two individualities." But neither the germ cell nor the sperm cell had itself been a higher animal and neither the one nor the other had ever been a somatic cell of an animal body. The theory of Darwin known as "natural selection" in the struggle for existence was, he contended, a complete fallacy, while Weismann's theory of germinal selection was a purely mental concept "quite without connexion with any known phenomena or epoch of development and hanging entirely in the air." As defined by Weismann this process would furnish a very great variety of gametes or conjugation cells so varied in their characters or qualities that the resemblances rather than the differences among the progeny would require explanation. Dr. Beard then proceeded to discuss the phenomena of fertilisation, and stated that in the line of development of the germ cells from the fertilised egg of one generation to the visible primary egg of the same generation in many invertebrates the intermediate cell generations were five or less, thus demonstrating a close relation of the germ cells. In vertebrates the number of intermediate divisions might be ten or less. As regarded the phenomena of variation the Darwinian theory *did not attempt to explain the* cause of variation but assumed its existence. The only adequate cause of variation yet suggested was Weismann's theory of amphimixis and germinal selection. But these were different from Nature's method which was slow and sure. When Nature caused variation she initiated it by altering the environment. While some one or more varieties of a species might be able to adapt themselves to the new conditions, others would fail in this, and these would be eliminated either as individuals or by germinal elimination. This explanation threw light on the Mendelian cases of intercrossing of peas, on mimicry, protective colouration, bud-variation, and the loss of organs such as the hind limb of the Greenland whale. Dr. Beard then referred to the positions occupied by Darwin and Weismann as regarded natural selection and germinal selection respectively and concluded that by his own discoveries he had "completely and decisively outflanked and rendered untenable" the positions held by Darwin and Weismann. He also referred to the inappropriateness and crisp, short, and well-arranged paper. He indicated the seat of so-called ovarian pain as corresponding to a point two inches internal to the anterior superior iliac spine in the area of the distribution of the tenth dorsal nerve to the abdominal wall. Pain at this spot was elicited on deep pressure and it was therefore thought that the pain was due to pressure on the ovary. He did not think that the pain was really ovarian. He divided the subject into three—the pain, its nature and causes, and its treatment. The so-called "ovarian" pain might be one of four kinds. 1. Peritoneal pain—outside the scope of the discussion. 2. Reflected pain from visceral disease. Reflected pain might be caused by disease of the subjacent ovary; if so, what was the disease? This kind of pain might also, however, be the result of disease of the bowel, the liver, the gall-bladder, the kidney, the ureter, or the Fallopian tube. When produced by disease of the ovary it was pain and tenderness of the skin and not of the ovary. Other causes not associated with signs of disease might bring about this pain. Two conditions of the ovary had been said to cause chronic pain: (*a*) sclero-cystic disease; and (*b*) cirrhosis of the ovary. Ovarian cystic disease was usually painless. The second was due to changes in the ovary no more painful than was the same condition in the lung, liver, or kidney. The fibrous after-stage of chronic inflammation of the ovary was not painful. Shrunken ovaries were not painful. There was, therefore, no reason why fibrosis of the ovaries should cause pain. Their knowledge of the pathlogy of ovarian atrophy was not very exact. He knew of no way of distinguishing between the various conditions which really caused the so-called "ovarian" pain. 3. Neurasthenic pain. When the resistance of the higher nervous centres was weakened from any cause, pain might become aggravated and extended or it might be manifested without existing disease. Among the weakening causes were: (*a*) anæmia, (*b*) cachexia, (*c*) fever, and (*d*) menstruation. The neurasthenic cause of pain was the most frequent to come under the notice of the gynæcologist. 4. Hysterical pain. This kind of pain did not confine itself to anatomical boundaries, and other signs of hysteria were usually present. The treatment of so-called chronic ovarian pain rested on the removal of its cause, which was often other than the state of the ovary, or depended on neurasthenia or was a manifestation of hysteria. He quoted many cases to show the futility of operative treatment of so-called ovarian pain and laid stress on the return of the pain soon after removal of the ovaries, igni-puncture, resection, or simple removal of cysts. The neurasthenic condition, he recommended, should be treated by tonics, rest, food and sleep, and cessation from a mode of life and surroundings which were conducive to a return of the neurasthenia, and the hysterical pain by suggestion and moral treatment, which must be kept up or the cases would tend to relapse. Operations often acted suggestively to the hysterical patient and so did only temporary good and therefore were not desirable. The reflected pain called for treatment by attention to the evidences of the existence of substantive disease such as erosions of the cervix, uterine conditions, disease affecting the ovaries, tubal conditions, inflammations, adhesions, and the like. He strongly deprecated opening the abdomen for ovarian pain purely, or the removal of the ovaries for pain without strong evidence that the pain was due to actual disease remediable by abdominal section apart from the neuralgic condition of the ovaries.

Mr. F. B. Jessett (London) said that in certain cases of pain complained of on the right side of the abdomen in the region of the tenth dorsal nerve distribution it was very difficult to distinguish between that referable to so-called ovarian pain and that due to chronic appendicitis. In the treatment of ovarian pain correct diagnosis of the real cause of pain in the locality was the very essence of the matter. He did not agree that there was no pain in sclero-cystic disease of the ovaries; the pain, indeed, was often acute, and if the ovary was removed the pain would disappear permanently. In many cases of cystic disease incision of the ovary and removal of the cyst were all that was necessary.

Dr. John Campbell (Belfast) thought that varicocele of the broad ligament ought to be considered as a cause of the so-called ovarian pain. Chronic constipation was also a cause of the pain and also tended to produce varix of the veins of the broad ligament, just as in the male constipation assisted to produce varix of the veins of the cord.

Dr. Herbert Snow (London) said that for the most part he entirely agreed with Dr. Herman's contentions. Constipation was often a cause of so-called ovarian pain. He did not think that hysteria and neurasthenia ought to be considered separately as a cause of ovarian pain. He also thought that irritable endo-cervicitis was often the cause of ovarian pain.

Mrs. F. N. Stanley Boyd, M.D. (London), said that it was well known that the variability of pain in pelvic organs was common and would account for much of the diversity of opinion entertained by members of the profession. She thought that varix of the broad ligament was possibly a cause of pain, especially in nurses and those who had to do much standing about, as female shop assistants. When it was said that ovarian pain was not due to fibro-cystic disease peritoneal adhesions must be excluded as undoubtedly they were the cause of much pain in some cases. In spite of what was said against operation for pain there were cases which were much benefited by operation and others by general improvement of health following on change of air and tonics.

Dr. Ewen J. Maclean (Cardiff) wanted to know how the differentiation of the various conditions was arrived at, for in his experience the matter was no easy one, as must be freely acknowledged by all present. He did not think that the removal of ovaries for ovarian pain would in the future be so frequently resorted to, if at all. Resection was now more usual than removal of the ovaries. He thought, however, that resection was often as great a failure as removal of the ovaries. In his experience neurasthenic cases were just those in which the ovarian pain was most acute.

Dr. Heywood Smith (London) also discussed the relative merits of operative and non-operative measures and laid stress upon the regions of the abdominal wall in which the reflected pain was manifested.

Dr. Cuthbert H. J. Lockyer (London) said that he had examined undoubtedly painful ovaries which had been removed but found no microscopical or pathological change which could be assigned as the cause of pain and the organs were evidently functionally useful. Visceral pain was more marked on the left than on the right side of the body, perhaps because there was some constitutional weakness on the left. Frequent child-bearing and hyperlactation were a fruitful cause of ovarian pain and he quoted a series of cases to show that the ovarian pain was invariably in the left tenth dorsal nerve area on the abdominal wall. He thought that practical medicinal treatment was the correct line and not the operative method.

Dr. Inglis Parsons thought that ovarian pain *quâ* pain had really no practical diagnostic value as regards operative or non-operative treatment. The pain in neurasthenic cases was often rheumatic in nature. The ovary was more often not the cause of the so-called ovarian pain. He was of the opinion that in some cases sclero-cystic disease was the cause of pain and quoted a case which had gone from consultant to consultant where he removed a small hard fibroid ovary and cured the pain complained of.

Dr. A. F. H. Rabagliati (Bradford) contributed an interesting and valuable item to the discussion in the form of photographs of the variable seats in the body of pain in certain women the subject of ovarian pain. He also showed a series of plates illustrating the exercises necessary for the alleviation of this condition. He contended that the rheumatic and gouty diathesis was commonly the cause of ovarian pain. The condition was really in the nature of a gouty or rheumatic effusion into the stroma of the ovary, just as it was elsewhere in the body. He did not believe in operative procedures, as the disease was in the connective tissues all over the body. The Weir-Mitchell treatment was most useful in many cases, and also regimen in diet, aimed at the aforementioned causes, would be found most useful.

Dr. W. E. Fothergill (Manchester) said that ovulation and ovarian pain were closely connected, as one or other ovary from month to month was usually the site of pain and the painful condition was usually attended with enlargement.

Dr. J. B. Hellier (Leeds) advocated examination under an anæsthetic in cases of so-called ovarian pain. The main object to be aimed at was to try to cure the pain without operative measures if possible. Those cases in which the ovaries were removed for pain and in which the ovaries showed no evidence of disease were always disappointing in their after-results in every way.

Professor J. W. Byers considered that the matter resolved environment. The public followed with keen interest their remarks in this section, and especially on heredity. To be delivered from the "dead hand" of heredity, to find a door of deliverance, was an object of eager longing to many. What was inherited was not a special alcoholic craving or a disease of distinctive type, but a morbid tendency of the brain, a fault which might by early and careful training and surroundings be overcome. A tendency to disease, such as gout, successfully resisted through three generations was stamped out in the fourth—that is to say, the fourth generation was born absolutely without any weakness or tendency to uricacidæmia and gout. In nurture and environment they had agencies of great potency which, if rightly employed, had considerable power to neutralise or thwart the evil influences and the fatalism of heredity.

Dr. C. R. **DRYSDALE** (London) stated that environment made up 99 per cent. of all the question of improvement of the race. Heredity was far too difficult a matter to be dealt with practically and he disagreed with the view recently advocated by Dr. Rentoul, Dr. Chapple of New Zealand, and others, that we should sterilise the epileptic, the insane, the inebriates, and confirmed paupers by some surgical operation. There was no question of the prevalence of physical degeneracy in this country when 77 per cent. of the population lived in cities and when out of 11,000 young men in Manchester who wanted to serve their country as soldiers only 2000 could satisfy the low standard of five feet three inches in height. He felt that the only way to improve the race physically was by improving the social and hygienic condition of the people.

[illegible]at the truth lay [illegible] Professor Karl [illegible] qualities are inherited as strongly as are stature and anatomical characters and the view of Dr. Beard that there was no hereditary transmission at all from parent to offspring. With a large personal experience of insanity he believed that heredity played a great part in disease and human degeneration, and this had been confirmed by the very able presentation of statistical data in Dr. König's paper. Dr. Jones related his experience in the study of slum and country children and said that there was more in heredity than could be established by the morphology and continuity of germ cells alone—which was Dr. Beard's ultimate criterion. He considered that bio-chemical and constitutional changes, which certainly existed but the presence of which was not revealed by the microscope, opened up fresh fields for investigation and research.

Mr. **JAMES STEWART** (Clifton) said that of the large number of cases of alcoholism and inebriety which he had under care during the last 20 years quite 50 per cent. were the issue of neurotic parentage. The parents themselves were not necessarily given to drink but exhibited some nervous defect or degeneracy. Similarly he had found inebriate parents whose children were particularly liable to [illegible]s one of the most [illegible]nd nurture were of [illegible] of life. Place, for [illegible] parent in favourable [illegible] he would [illegible]ay escape the risk of [illegible]elf an alcoholic.

[illegible]YMOUR **TUKE** (London) inquired whether any [illegible]own of a general paralytic begetting a son who [illegible]f life would develop general paralysis without personal predisposing cause.

Dr. G. F. **BLANDFORD** (London) said that the environment was a powerful agent [illegible] of insanity. If they could [illegible] patients and have them [illegible] far fewer would become insane than if they were permitted to live with their parents.

Dr. **DAVID YELLOWLEES** (Glasgow) believed that the subject of heredity was really most difficult to understand. If the germ cell in its development pursued a course *altogether fatalistic, one regardless of all* influence proceeding from the environment in which it developed, then moral [illegible]ponsibility was reduced almost to a myth and conscience [illegible] delusion. The transmission of parental qualities in [illegible]ct of bodily and mental traits could not for a moment [illegible]ubted by any physician of experience.

[illegible] F. **MAY DICKINSON BERRY** (London) inquired whether [illegible]as any difference in the liability to insanity of [illegible]rn after the father had become insane compared [illegible]en born prior to his insanity and also whether the [illegible] a tuberculous father begotten by him before and after tuberculous infection were differently constituted as regards health of body and mind.

The **PRESIDENT** (Dr. C. A. **MERCIER**, London) remarked upon the importance and intricacy of the phenomena of heredity and briefly referred to the necessity of correct views in the matter in regard to the improvement of the race.

Dr. **BEARD** and Dr. **KÖNIG** then briefly replied to the questions asked in the course of the above discussion.

PHYSIOLOGY.

THURSDAY, JULY 28TH.

Professor E. W. **WACE CARLIER** (Birmingham) read a paper on

Histological Changes in Liver Cells during Activity.

[illegible]le rats were after a period of [illegible] diet divided into four batches [illegible]or several days on four different diets—(1) mixed, (2) proteid, (3) carbohyrate, and (4) fat. After 24 hours' starvation one animal in each batch was killed and the remainder were given a full meal of the special kind to which they had been accustomed, one from each batch being then killed off hour by hour and the livers appropriately preserved for microscopic examination. In the fasting rats were minute highly refractive granules of a greenish-grey colour which had disappeared an hour after the meal and did not reappear even in 12 hours. In all were clumps of a structureless material, not [illegible] eosin and iron-alum- [illegible] however, after a long [illegible] the same whatever the diet, but least marked on a carbohydrate one. Two distinct periods of nuclear activity were recognisable after a meal, the first commencing directly and lasting until the third hour, and the second beginning four or five hours after the meal and of longer duration. During these periods the nuclei became less plump and showed changes similar to those previously described by Professor Carlier in the oxyntic cells of the newt's stomach. These changes he regarded as pointing to the formation of an enzyme. A remarkable feature was the rapid vacuolation of the cytoplasm noted one hour after the meal, disappearing one or two hours later. About the sixth hour the cells swelled up and glycogen accumulated in abundance.

Dr. K. A. **GROSSMANN** (Liverpool) read a paper on

Further Investigations on Accommodation.

Analysis of a case of astigmatism with excentricity of the pupil where the axis changed during accommodation showed that this changing of the axis was due to a lateral displacement of the entire lens during accommodation, as demonstrated by Dr. Grossmann last year in a case of aniridia. This excentricity and ovality of the pupil had led him to investigate the accommodation changes in eyes with slit-shaped pupils. The eyes of cats under the influence of eserine and atropine were frozen by solid carbon dioxide and the shape of the lens was observed in section. Under the influence of eserine the lens showed a very marked posterior lenticonus with its apex above the optical axis. Thereby a [illegible] astigmatis[illegible] the slit-shaped [illegible] astigmatism and so neutralised it. Here for the first time was given an explanation of the shape of the pupil in the cat. Dr. [illegible] to show this vertical astigm[illegible] on cats and *examining the* [illegible] had been able to disprove the assertion of Hess that the range of accommodation in the cat was practically *nil;* it was, on the contrary, considerable. Finally, he argued that the iris was more important as an optical (stenopæic) diaphragm than as a light screen. A large number of slides illustrated this paper.

Dr. **GROSSMANN** read a second paper on

The Purkinje-Sanson Reflex Image of the Anterior Lens Surface.

In observing Purkinje-Sanson reflections from the anterior surface of the lens an angle of incidence of 60° was better than one of 30° as used by Helmholtz. It was easy by this means to obtain reflex images from the circumpolar and peripheral parts of the anterior lens surface but it was in the overwhelming majority of cases impossible to get any reflection from the centre. The centre of the lens was, in fact, not spherical either in young or old, atropinised or normal eyes. By careful observation the reflex image was seen to be interrupted by black lines which formed the figure of a six- or seven-rayed star corresponding to the architecture of the lens. The reflection took place, therefore, at some surface lying deeper than the lens capsule, since the latter did not take part in the radiate arrangement of the lens fibres. Observations on a case of polar cataract showed that the reflecting surface dipped inwards towards the centre of the lens at the margin of the small cataractous opacity, although the anterior surface of the lens capsule was of quite normal shape.

Professor J. A. **MacWilliam** (Aberdeen) read a paper on

Some Points in the Physiology of the Mammalian Heart.

The spontaneous rhythmic beat of the heart might be observed to originate not only in the terminal parts of the vena cava but also in the coronary veins. Vagus excitation even when strong did not diminish the direct excitability of the ventricle; its effects were purely upon the force of the contraction. Contrary to general belief the rhythm of the heart, the connexion of which with the central nervous system had been severed, was remarkably insensitive to changes of blood pressure within wide limits, although the contractile force was very readily affected. There was no trustworthy experimental evidence that the cardiac augmentor nerves could be excited reflexly or by cerebral anæmia or asphyxia. The peripheral efficacy of the vagus was not markedly affected by asphyxial blood or within wide limits by changes of arterial and venous pressure. After asphxyia had reached a certain stage readmission of air into the lungs was followed by an excessively rapid heart-beat.

Dr. **Hugh Maclean** (Aberarder) communicated a paper on

The Action of Muscarin and Pilocarpin upon the Heart.

The paper, which was read by Professor **MacWilliam**, showed that in the heart of the frog, the newt, and the eel the "survival time" and the efficacy of the inhibitory mechanism underwent marked seasonal variations. Muscarin and pilocarpin were more or less effective in exact correspondence with the varying efficacy of the inhibitory mechanism as tested by direct electrical excitation. This parallelism was equally marked in different isolated portions of the heart and showed that the two drugs investigated acted on the inhibitory mechanism and not directly on the cardiac muscle. Since the apical portion of the newt's heart could be inhibited by muscarin and pilocarpin and the inhibition was done away with by atropin, and yet this part was free from ganglion cells, these drugs must act upon the terminal portion of the inhibitory mechanism.

Professor **Carlier** read a paper on

The Elastic Tissue of the Eyeball.

More elastic tissue was found in the eyes of birds than of any other class of vertebrates and especially in birds that accommodated strongly to pick up small objects. The eyes of other members of the sauropsida, such as lizards, did not possess elastic tissue at all. The so-called elastic fibres which Tartufieri and others had described in the cornea and in Descemet's membrane did not stain with Weigert's stain unless this was reinforced by orcein, and they were not composed of elastin but of a chemically allied substance.

A joint meeting of the Section of Anatomy and Physiology was held under the chairmanship of Professor **Arthur Thomson** (Dublin) and later of Professor F. **Gotch** (Oxford) to discuss

The Thalamic Region.

The subject was introduced by Dr. **Gustav Mann** whose remarks are reported under the proceedings of the Section of Anatomy. Among the points of special physiological interest may be noted Dr. Mann's observation that removal of the olfactory lobe in young rabbits was invariably fatal, owing to loss of the sense of smell. Dr. Mann divided the thalamus into a dorsal and a ventral portion, the fillet fibres terminating in the anterior part of the latter. The dorsal portion, with the exception of the tænia thalami, ganglion habenulæ, and fasciculus retroflexus, served to connect the thalamus with the cerebrum. The effects of removal of the cerebrum, middle ear, and eyes were explained with the help of 60 diagrams representing the nuclei of the thalamus of the rabbit.

Dr. W. **Page May** (London) described the effects of one-sided lesions of the thalamus performed for him by Sir Victor Horsley. The most notable symptoms were paralysis and anæsthesia of the opposite side of the body, hæmianopia, and turning of the face to the side of lesion with the opposite ear depressed to the opposite shoulder. In some cases the opposite pupil became larger than that of the same side.

FRIDAY, JULY 29TH.

Sir **Victor Horsley** in introducing the discussion on

Chloroform Anæsthesia

pointed out that the appointment of the special chloroform committee of the British Medical Association was the result of Dr. Waller's suggestion that death during chloroform anæsthesia was due to overdose. The committee was instructed to determine quantitatively the percentage of chloroform in the air breathed and in the blood. In its labours it had been so fortunate as to secure the help of Mr. Vernon Harcourt who had devised a simple apparatus by which it was possible to regulate the percentage of chloroform vapour in the air breathed. This apparatus was, in the opinion of the committee, by far the most suitable yet devised and if shaking was avoided it delivered air containing at most 2 per cent. by volume of chloroform vapour. Error due to changes of temperature in the chloroform was avoided by the introduction of coloured beads of different specific gravity which served as indicators of such change. It was as necessary to know the dose of chloroform given as of any other drug, and Harcourt's apparatus enabled them to do so. In children a percentage of 1·5 was often sufficient to induce anæsthesia. After some 20 minutes the percentage required to keep up the anæsthesia fell enormously and might sink to nothing during as long as 20 minutes. Du Bois's apparatus weighed a quarter of a hundredweight and had the disadvantages inseparable from any type of "blow-through" apparatus.

Professor B. **Moore** (Liverpool) described experiments conducted in association with Dr. H. E. Roaf showing that chloroform formed easily dissociable compounds or aggregates with the proteids of the blood and tissues and argued that the production of anæsthesia was due to this fact. The aggregations only existed so long as an adequate pressure or concentration of the anæsthetic was kept up in the surrounding medium. Their existence was shown (1) by the greater solubility of chloroform in serum or solutions of hæmoglobin than in salt solution—e.g., serum dissolved five times as much as water or normal saline solution; and (2) by the fact that at equal concentrations the pressure of the anæsthetic (measured by the differential densimeter, an instrument specially designed for this purpose) was much lower in serum or blood than in water or saline solution. With increasing concentration of chloroform in the air breathed the amount of chloroform in the blood was found to increase at a proportionately greater rate. From experiments upon cardiac tissue and cerebral tissue he had come to the conclusion that chloroform produced its effects by acting upon protoplasm and not upon such substances as lecithin or fat and that these effects were proportional to the concentration or osmotic pressure of the anæsthetic at any given time.

Mr. E. S. **Edie** had, in conjunction with Professor Moore, investigated the precipitates produced by chloroform in solutions of hæmoglobin and serum. One and a half per cent. of chloroform produced a precipitate in the former when kept at blood temperatures. With higher percentages the solution first became brick red and then opaque. The precipitate could be washed with water and was practically insoluble in it. When exposed to a low pressure this washed precipitate gave off considerable quantities of gas, presumably chloroform. It was readily soluble in sodium hydrate and sodium carbonate solutions. When the percentage of chloroform was insufficient to cause a precipitate in hæmoglobin solutions the compound was salted out by saturation with ammonium sulphate. Determination of the chlorine in the salted out and precipitated compounds showed that this was approximately constant. With carbon-monoxide hæmoglobin much more chloroform was necessary to cause precipitation.

Professor C. S. **Sherrington** (Liverpool) stated that his experiments on the effects of perfusing blood-containing chloroform through the isolated mammalian heart showed that with heavy doses a permanent damage was inflicted which could not be removed by any amount of perfusion with saline solutions free from chloroform. With lighter doses the cardiac beat was depressed and the amount of the depression was graded by the tension of the chloroform in the liquid [illegible] perfusing [illegible] when the [illegible], for equal [illegible] chloroform in blood. The animal principally used was the cat. He had never observed changes in the rhythm of the isolated heart as the result of chloroform.

Professor S. H. C. **Martin** (London) called attention to Embley's experiment in which chloroform-air mixture in known percentages was supplied through the lungs to an isolated heart and lungs. With 0·8 per cent. of chloroform vapour the heart became motionless in 16 minutes, with 1·2 per cent. in nine minutes. In an intact animal it would take five or six hours to produce the same effect, a fact which the speaker attributed to the increased quantity of blood and tissues absorbing the chloroform and keeping its tension low.

Professor **MacWilliam** stated that in relatively slow poisoning by chloroform when a considerable amount had been given there was depression of the respiratory centre, arterial tone, and of the heart, but the state of the heart was the most serious bar to recovery. In sudden death at comparatively early stages of anæsthesia vagus inhibition might, he pointed out, be largely responsible, the blood flowing slowly through the lungs becoming over-charged with chloroform and producing fatal damage when distributed through the coronary arteries to the heart. It was very important to aim at obtaining steady intake and distribution of the anæsthetic. Given a definite percentage in the air the amount reaching the heart per unit of time might vary (1) from variations in the amount of air breathed, and (2) from variations in the blood current through the lungs; and these variations were especially apt to occur during imperfect anæsthesia. It was often impossible to determine post mortem whether death had occurred from asphyxia or from syncope, since post-mortem rigor in the heart might cause a heart paralysed by chloroform to show the features commonly associated with death from asphyxia.

Dr. **Dudley W. Buxton** (London) stated that although it was once taught that dangers due to reflex cardiac inhibition could be abrogated by giving a larger percentage of chloroform vapour in the air [illegible] that reflex inhibition mi[illegible] were used. The suppos[illegible] due to the fact that complete anæsthesia had not been attained before operative measures had been commenced. In his experience 2 per cent. of chloroform was adequate in most if not in all cases and when a higher percentage than this was used it should only be with special reasons and with a full recognition of the danger of the proceeding.

Professor **Waller** criticised the apparatus devised by Vernon Harcourt on the ground that it established a vicious circle in which, as had been admitted, a rising percentage of chloroform vapour accompanied falling respiration and also that perfect tranquillity of the chloroform surface, although an absolute necessity, had not been secured. The clinical report on the utility of the apparatus had not been either complete or impartial. He thought that the method used by the Chloroform Committee of the British Medical Association for estimating the chloroform of blood was, however ingenious, very laborious and necessarily inexact.

Dr. W. J. **McCardie** (Birmingham) had, using Harcourt's apparatus, anæsthetised ten adults with 1 per cent. of chloroform vapour in the air and had found the average period before the lid reflex was much dulled or abolished to be 16½ minutes; with 1·5 per cent. in ten cases it was 12½ minutes. He had found that, beginning with ethyl chloride followed by ether for five minutes, he could maintain anæsthesia with just about 1 per cent. of chloroform and thought this a very advantageous method. He recommended that induction of anæsthesia should be begun with 1 per cent. to 1½ per cent. of chloroform, but for alcoholic patients the Harcourt apparatus should be modified so that larger percentages could be given. The great principles of graduation of dosage [illegible] on and regulation of dosage [illegible] hesia could be perfectly carried [illegible] and the danger of overdosage [illegible]. The main features of the anæs[illegible] were: (1) the quiet and regular induction with absence of mental and muscular excitement; (2) the comparative lightness and yet efficiency of the anæsthesia; (3) the perfect control; and (4) the quick recovery and small after-effect.

Dr. **Paul M. Chapman** (Hereford) exhibited and described Du Bois's apparatus for administering chloroform. This apparatus furnished a constant flow of air containing chloroform vapour in known percentages independently of any suction efforts on the part of the patient. It was easy to obtain within minute limits faithful percentages of 1·2, 1·6, or 2·0, the latter being just sufficient to produce complete surgical anæsthesia without reflex movements. The apparatus was worked by turning a handle about six times a minute, each revolution delivering four litres of the chloroform-air mixture. It was impossible to exceed 2 per cent. of chloroform unless the apparatus was shaken. The average time occupied in producing complete anæsthesia was eight minutes and he had found administration of chloroform by this instrument most trustworthy and relatively free from danger.

Dr. H. O. **Crouch** (London) had avoided fallacies due to shaking of the Harcourt apparatus and had found that on the average it took 20 minutes to induce anæsthesia. When, however, the breathing was shallow the patient went under quickly and there was grave danger of an overdose. He held strongly that the apparatus was ineffective and depended largely on the accidental element of shaking.

Dr. A. G. **Levy** (London) stated that he had estimated by Harcourt's combustion method the percentage of chloroform vapour in air sucked through a Harcourt's inhaler in the same quantities as those occurring clinically. With varying rates of air-flow he found, with the index at 2 per cent., amounts varying from 2·02 to 1·38 per cent. Even a slight shake raised the percentage to 2·73, while a stronger one raised it to 5. Having illustrated practically that it was possible to shake the bottle Dr. Levy stated that Harcourt's apparatus did not fulfil the essential requirements of a chloroform inhaler—viz., "that it should tell us to a nicety what strength of vapour the patient was breathing."

Sir **Victor Horsley** replied to the various criticisms to which Harcourt's inhaler had been subjected.

ANATOMY.

Thursday, July 28th.

Dr. R. J. A. **Berry** (Edinburgh) and Dr. H. D. **Shepherd** (Edinburgh) gave a demonstration on

Cranio-cerebral Topography,

illustrated by lantern slides and five casts. They had recently been engaged in an investigation of the methods associated with the names of Hare and Thane, Chiene and Reid. In each instance the brain had been thoroughly hardened by means of formol injections on the undissected subject and the guiding lines employed by each of the three methods under investigation were then drawn on the skull, all intermediate portions of the bones being afterwards removed by Hey's saw. The result was a clear demonstration of the positions of the various fissures and convolutions of the brain and their relations to the osseous bars which indicate the guiding lines of the method employed. The conclusions which had been arrived at were that Hare and Thane's method gave the fissures of Rolando and Sylvius fairly accurately, whereas Chiene's method only marked out the Rolandic area correctly in 43 per cent., and, moreover, that Reid's method was altogether inaccurate for marking out the fissure of Sylvius. Hare and Thane's method was therefore to be regarded as the most accurate of all those methods which they had submitted to investigation and the most generally applicable of all methods of cranio-cerebral topography.

Professor **Johnson Symington** (Belfast) inquired whether the material which had been worked with was perfectly fresh or whether there were any shrinking and accumulation of fluid due to old age.

Professor A. **Thomson** (Oxford) and Professor G. D. **Thane** (London) also spoke and, in reply, Dr. **Berry** stated that the greatest care had been taken, and though the method was excessively laborious it gave the utmost precision obtainable and constituted a severe proof of the accuracy or otherwise of the particular method investigated.

Mr. J. W. **Jenkinson** (Oxford) followed and demonstrated by means of the lantern and the microscope

The Arrangement of the Maternal and Fœtal Glycogenic Cells in the Placenta of the Mouse.

He stated that glycogen was found first of all in the maternal cells which overlay the allantoidean portion of the trophoblast and that these cells reached their highest phase of development in about 12 days or at the time when the allantoic villi began to penetrate the trophoblast. They were rounded and separated from one another by elongated, fusiform, or stellate supporting cells and each contained a rounded nucleus with one nucleolus. At this time mitoses were no longer to be found in the cells. In the next stage the uterus had by the growth of the embryo increased considerably in size, but the cells of the maternal glycogenic tissue had ceased to multiply, were incapable of keeping pace with this increase of volume, and were necessarily separated from one another. They then began to disintegrate and eventually degenerated and disappeared. Meanwhile another glycogenic tissue of trophoblastic—i.e., fœtal—origin had begun to make its appearance. The trophoblast of the placenta was divisible into two portions: (*a*) an allantoic portion on the fœtal side penetrated by the capillaries of the allantois, and (*b*) a glycogenic portion between the allantoic trophoblast on the one side and the maternal glycogenic layer on the other, traversed by maternal blood but not invaded by the fœtal vessels. The cells of this layer secreted glycogen; they were closely packed, oblong in shape, and their nuclei were oval and contained more than one nucleolus. In the subsequent stages of placentation the glycogenic trophoblast encroached more and more on to, and occupied the space previously filled by, the maternal glycogenic cells, ultimately reaching the muscularis. Soon the maternal glycogenic cells showed diminution in numbers and eventually completely disappeared. Towards the end of gestation the glycogen disappeared from the glycogenic trophoblast also, the cells of which collapsed. Mr. Jenkinson thought that this might possibly play some part in determining the moment of parturition as it was across the zone of trophoblastic glycogen cells that the placenta broke away from the uterus.

Professor A. H. YOUNG (Manchester) and Professor ARTHUR ROBINSON (London) communicated some observations on

The Development and Morphology of the Tail.

So far as its functions were concerned the tail of vertebrated animals was admittedly an appendix, but, on the other hand, so far as its development and its general structure were concerned, it had been regarded as morphologically identical with the body itself. If, moreover, the structural elements of the body and the tail were morphologically equivalent the tail, like the body, must be segmental, the segments of the two parts should be of similar value, and their constituent elements should play relatively similar parts in the general economy. The constitution of a typical segment was then described and this was contrasted with a tail segment, and it was shown that the tail of any adult tailed mammal possessed many of the factors that were to be regarded as characteristic of a typical segment, but not the whole of them, for some essential parts were suppressed. For example, the visceral tube was absent and the spinal cord was limited in extent. The ontogeny of the tail helped to confirm and to emphasise the adult anatomy, for it demonstrated clearly that the tail possessed some and was devoid of other important constituent parts of somatic structure. At all periods it was devoid of excretory system and cœlomic space. It possessed blood-vessels and so far as the artery was concerned it simulated, but it was not simply a continuation of, the dorsal aorta of the body somites. Its spinal and sympathetic ganglia were few and it was doubtful if they belonged in reality to the tail somites proper or were merely displaced ganglia from the somatic region. The nerves were derived from the "caudal ganglia," from the posterior somatic ganglia, and the somatic neuromeres of the spinal cord. The muscles were derived from muscle plates which greatly exceeded in number the caudal ganglia and the ventral roots which came from the caudal segments of the spinal cord. The fact that the muscle plates considerably exceeded in number the caudal ganglia and the ventral roots was one of the most striking features of the anatomy of the tail, for it proved that the rule of the muscle deriving its nerve-supply from the same segment was no longer applicable to every part of the body, for in the tail it was certain that many of the muscles were supplied by nerves of more anteriorly placed segments. Amongst the conclusions at which Professor Young and Professor Robinson had arrived as a result of their investigations were that the tail was not merely a backward prolongation of the body, consisting of the same dorsal and ventral parts, but that it was the result of the energy of a growing point which contributed to the formation of the body as well as the formation of the tail. In its widest sense the tail was an appendage to the body and its nervous and vascular supply were dependent on the nerves and vessels of the body which had been prolonged into it.

The rest of the morning was occupied by an important discussion which took place, jointly with the Physiological Section, on

The Thalamic Region.

Dr. GUSTAV MANN (Oxford), who opened the discussion, first drew attention to a fundamental division of the nervous system into two parts, a part in front of and a part behind the posterior commissure of the brain. The part anterior to the commissure he called the thalamus and the part behind, which included the medulla, the pons, and the mesencephalon, he called the cord. At first the two parts were functionally as well as anatomically distinct, for the cord had from the commencement a sensory and motor mechanism, whereas the thalamus was primarily sensory and later the motor mechanism became superadded by means of the cortex and the corpus striatum. The thalamus through the olfactory and optic outgrowths became connected with the olfactory and visual cells and through the red nucleus it became connected with the cord. Dr. Mann regarded the retina, with the exception of the layer of rods and cones, as part of the thalamus and described how the thalamus became further joined to the cord through the sense of touch by means of the fillet. After having thus detailed the various stages in the development of the thalamus he showed an extensive series of drawings of the various thalamic nuclei and agreed with the primary division of the thalamus into dorsal and ventral parts by the falciform nucleus of Ramon y Cajal. The oldest nucleus of the thalamus was the ganglion habenulæ, a nucleus developed in the tænia thalami and persisting after removal of the cerebrum.

Sir VICTOR HORSLEY (London) followed and agreed with the morphological conclusions of Dr. Mann and particularly as to the division of the thalamus into dorsal and ventral portions, according to the original view of Burdach, and he also agreed that the ventral division of the external geniculate nucleus had different pallial relations from the dorsal division. Further, he discussed the minute structure of the ventral division of the thalamus and showed that the extremely restricted termination of the fillet axones as localised by the degeneration method was now confirmed in the most recent publication by Ramon y Cajal. Both methods tended to show that the "fillet nucleus" consisted of three parts, a central globular portion to the opposite sides of which two semilunar nuclei were applied. Further, he asked—What was the morphological unit wherewith to divide the thalamus? He thought that the plexuses of fibres should not be dwelt upon for subdivision of the thalamus but that the true morphological limit was the cell. What neurologists wanted for the analysis of function was the most minute description of the nuclear collections of cells.

Professor F. GOTCH (Oxford) thought that the most important side of the thalamus was afferent and that the efferent was superadded.

Dr. W. B. WARRINGTON (Liverpool) drew attention to Probst's works on the subject of the thalamus. For himself he regarded the thalamus as a great relay centre, receiving the terminations of nerve fibres from the pallium, cerebellum, &c.

Dr. W. PAGE MAY (London), who had been working at the subject in monkeys, gave a most interesting account of the results of lesions in the thalamus and detailed the symptoms produced. He had found in a large number of cases hemi-anæsthesia and hemianopsia of the opposite side of the body, as was found in the classical case in man described by Dr. Hughlings Jackson in 1874. In addition he found in about half the cases a most interesting symptom which consisted in a deviation of the face and head to the same side as the lesion whilst the opposite ear was drawn down to the shoulder. In 15 out of the 16 monkeys on which he had experimented he found paralysis on the opposite side due to implication of the fibres of the pyramidal tract. In 11 there was anæsthesia on the opposite side; in several cases the contralateral pupil was larger than the pupil on the same side as the lesion, and nystagmus was occasionally present.

Sir VICTOR HORSLEY and Dr. MANN replied briefly.

FRIDAY, JULY 29TH.

The meeting of the section on Friday was held in conjunction with the Anatomical Society of Great Britain and Ireland. Professor JOHNSON SYMINGTON (Belfast) was in the chair and a large number of members and visitors were present.

Professor EDWARD FAWCETT (Bristol) read a preliminary communication on

The Ossification of the Lower Jaw in Man.

He first discussed the ossification of that part of the mandible from the region of the mental foramen to the middle line. As was well known Meckel's cartilage itself was directly converted into bone in this situation, but what he desired to emphasise was that Meckel's cartilage was not the only factor in the formation of the "symphysial" portion of the lower jaw but that it was covered in this position by a membranous structure which also became converted into bone and that this ossification was continuous with the so-called dentary centre. Towards the end of the second month a cartilaginous mass appeared in the condyle and extending down through the neck and root of the coronoid process reached the level of the lower end of the anterior border of that process. He doubted if any separate "splenial" centre was ever developed and also if any "angular" mass of cartilage appeared and became secondarily ossified. The appearances of the specimens which he had examined suggested that probably the whole membranous part of the jaw developed from one centre, but his specimens were not young enough to enable him to speak definitely on this point.

Dr. A. KEITH (London) asked whether the cartilage of the condyle and coronoid processes were formed independently of Meckel's cartilage, and Professor ROBINSON whether the Meckelian centre was independent of that in the surrounding membrane or not.

Dr. A. LOW (Aberdeen) confirmed Professor Fawcett's observation that the "dentary" centre appeared in membrane and extended forwards as a plate of bone right up to the middle line in front. From the dentary plate a shelf grew upwards and inwards for the support of the tooth germs, while Meckel's cartilage lay below the plate. Dr. Low, however, had observed that distinct cartilaginous masses appeared in the condyle, the coronoid process, and the angle, and these in turn underwent ossification. In certain mammals these cartilaginous nuclei were much more definite than in man and clearly had no connexion whatever with Meckel's cartilage.

Professor FAWCETT said, in reply, that the cartilage of the condyle and coronoid processes were developed long after the Meckelian cartilage and that the centre of ossification which appeared in the latter in the neighbourhood of the symphysis was independent of that in the surrounding membrane.

Dr. H. W. MARETT TIMS (London) gave a demonstration on

The Significance of Certain Epithelial Masses in Connexion with Developing Teeth,

illustrated with lantern slides. He pointed out that when the jaws of fœtal mammals of various stages were examined certain spherical epithelial masses, lying to the labial side of developing teeth and connected with the neck of the enamel organ, could be observed. Such spherical masses had already been seen in connexion with the fourth premolar of the dog and gymnura and with the so-called molars of the guinea-pig. They were also to be seen to the labial side of the first incisor, the second incisor, and the canine teeth in the human fœtus of three months. In these examples the masses were composed of distinct epithelial cells forming a spherical mass, with a neck, at first widely open and directly continuous with the cells of the dental groove. In a four and a half months' fœtus these bodies were still to be seen lying close to the edge of the jaw, but the cells had become more elongated, concentrically arranged, and distinctly granular. From the constancy of their position in relation to a developing tooth, from their temporary existence, and from their spherical shape they had, Dr. Marett Tims thought, some morphological significance. The only suggestion which occurred to him was that they represented vestiges of a previous dentition. If this were so then the human fœtus showed better marked vestiges of a pre-milk dentition than any other animal with which he was acquainted.

Professor D. J. CUNNINGHAM (Edinburgh) gave a lantern demonstration on

The Varying Form of the Stomach in Man and Anthropoids.

The first part of the paper confirmed and to some extent supplemented the observations of Professor His as detailed in his paper published last year in the *Archiv für Anatomie.* The second part of the paper dealt with certain physiological conditions of the stomach which were now frequently seen in formalin-hardened subjects. The condition especially dealt with was one in which the stomach presented a capacious cardiac part and a long, narrow, tube-like pyloric part. Professor Cunningham showed that this was not a gastric state which could be explained by tight lacing as was inferred by Professor His. He exhibited slides in which it was evident in two males, a female, and also in the stomach of a full time fœtus, and he referred to Mr. Cannon's observations on the movements of the stomach of the cat as observed by means of the x rays. In the third part of the paper the question of hour-glass stomach was discussed and Professor Cunningham supported the views of Mr. B. G. A. Moynihan. He held that this form of stomach might be due to physiological and to pathological causes, but it had yet to be shown that it ever was a congenital condition. The slide of a stomach of a full-time fœtus divided by a physiological constriction into a cardiac expanded part and a tube-like pyloric part was shown.

Dr. A. KEITH (London) drew attention to the fact that formalin seemed to pick out certain parts of the viscera which during life were in a systolic condition, so that by this means a somewhat similar condition was reproduced after death. In this way he explained certain constrictions which were to be seen along the alimentary canal in formalin-hardened bodies.

Dr. W. WRIGHT (Birmingham) thought that formalin did not afford a satisfactory explanation of constrictions. He had seen them during life and in two cases after death.

Professor A. ROBINSON (London) argued that the constrictions were irregularly arranged and not definite in position. They also varied in different individuals.

Professor J. SYMINGTON (Belfast) believed that with formalin the constrictions were more fixed than formerly when chromic salts were used. He supported Professor Dixon on the rarity of the empty diastolic condition.

In reply, Professor CUNNINGHAM thought that the action of formalin was purely a fixative one.

Professor F. KEIBEL (Freiburg) showed a series of models illustrating

The Development of the Uro-genital System, the Liver, the Pancreas, and the Spleen of Echidna.

Some of his more important results were as follows. 1. The mesonephros was very highly developed. It possessed large numbers of well-developed nephrostomes and it was probable that it was associated in function with the kidneys for some time after the animal was hatched. 2. The rudiments of the cortex of the suprarenal bodies appeared very early, arising from the cœlomic epithelium. The medullary portion of the suprarenals was derived from the sympathetic system and united with the cortex at a very late period in the development of the animal. 3. The ureter, the pelvis, and the tubuli recti arose from the Wolffian duct, whereas the glomeruli and the remainder of the uriniferous tubules were derived from the renal blastema. 4. There were two ventral and one dorsal pancreatic rudiments and all three produced pancreatic tissue. 5. The spleen of the echidna was derived, as in all other mammals, from the mesoderm of the dorsal mesogastrium. It had nothing to do with the entoderm and the pancreas rudiment.

Dr. J. D. LICKLEY (Manchester) read an interesting paper on

The Morphology of the Intertransverse Muscles,

and showed the relations of these muscles to the intercostals and the interarticulares.

Dr. J. CAMERON (St. Andrews) submitted a contribution on

The Ontogeny of the Neuron in Vertebrates,

and illustrated his remarks by lantern slides. His observations showed that the neuroblasts were really nuclei possessing no cytoplasmic envelope whatever. The rudiments of the axis cylinders arose in the form of protrusions from these nuclei. The results therefore gave support to the theories of His and Kölliker, and were, on the other hand, at variance with the theory

of nerve fibres. In reply to

gave an account of his fixative

Dr. ALEXANDER LOW (Aberdeen) described some

Skeletons obtained from Short Cists found in the North-east of Scotland.

He said that the mode of burial and the pottery found alon with the skeletons had characters usually assigned to the bronze age but the skeletons themselves exhibited certain characters differing from those usually ascribed to bronze-age skeletons in Britain. The skulls were very broad, and six out of ten which he examined were hyper-brachycephalic. The face showed no trace of prognathism, the mean gnathic index being distinctly less than that of the average modern Scottish skull. The lumbar vertebræ of one skull exhibited characteristics of the lumbar spine in the dark races. As regards stature, Dr. Low estimated that in six males the average height was five feet three inches, whilst one female must have been just under five feet. After contrasting the skeletons with the ordinary type of bronze-age skeleton Dr. Low referred to the affinities of the short-cist people. He thought they must be descended from the short broad-head Alpine race that occupied central Europe in late neolithic times. It was, however, difficult to see how they came to the north-east of Scotland.

Dr. WRIGHT said that the skulls were of the type named by Sergi *sphenoides tetragonus*, and although the race in the north-east of Scotland was almost a pure brachycephalic one, in cists in Yorkshire of the same period long-skulled populations had been found buried with round-headed ones.

Dr. OTTO GROSSER (Vienna) read a paper on

The Metameric Structure of the Skin in Vertebrates.

After referring to the work of Sherrington and Head he proceeded to contrast the stripes and lines on the fur of certain mammals with the innervation of the skin. The latter part of his paper dealt with the segmental distribution of the arteries of the skin in man, and his researches had confirmed those of Manchot that the distribution of the arteries to the skin was, unlike the nerves, subject to considerable irregularity. Frequently arteries of certain segments were missing and replaced by branches from neighbouring segments.

PATHOLOGY.

FRIDAY, JULY 29TH.

Professor VON NOORDEN (Frankfort-on-the-Main) introduced a discussion on Gout in a paper entitled

The Chemical Pathology of Gout.

After a comprehensive review of all the ascertained and established facts relating to the metabolic processes in gout he summarised them by stating that the oxidising energy of metabolism was not altered; the metabolism of albumin exhibited greater variations than in the healthy, and an increase in the elimination of nitrogen and phosphoric acid appeared during the attacks as well as in the intervals which pointed to the coöperation of endogenous toxic substances the nature of which was unknown. The influence of gout on the functions of the stomach and intestines was discussed and it was pointed out that the irregular results of this influence possessed no specific significance; the excess of nitrogen in the fæces was probably the result of increased nitrogen secretion into the intestinal canal. Endogenous (from the nuclein of the body), exogenous (from the nuclein of the food), and synthetical formation of uric acid took place; the other purin substances were stated to be, in comparison with uric acid, of minor importance. While endogenous uric acid formation did not show any material alteration in quantity from that observed in health, many minor yet important characteristics were observed with regard to exogenous uric acid, particularly in the direction of spontaneous fluctuations in the intervals between the paroxysms. In gouty patients, too, the rise of uric acid after the ingestion of purin substances appeared to be much more delayed than in the healthy. This and other observations pointed to the conclusion that retention of uric acid occasioned gout and was followed by a rise in the uric acid of the urine. Normally only traces of uric acid appeared in the blood, but increase followed over-feeding healthy individuals with purin bodies, although no gouty deposits could be produced. Gouty deposits in the tissues consisted of sodium biurate and it was suggested that acute gouty inflammation depended on the sudden solution of the crystalline deposit, the solution being effected by phagocytic action, not by alterations in the alkalinity of the blood. The theory was put forward that the normal organism elaborated certain organic substances with haptophoric side chains which combined with. and dissolved, uric acid, so removing it from its source of origin by means of the blood and presenting it to the kidneys in a form easily eliminated, whilst the gouty individual manufactured these organic substances in too small quantities. In conclusion the various therapeutic measures at the disposal of the physician and the indications for their exhibition were briefly discussed.

Dr. A. E. GARROD (London) was then called upon to read his paper, bearing a similar title to that of Professor von Noorden. He pointed out that the chief known data bearing on the pathology of gout centred round uric acid and its compounds but that the failure to explain the disease by a study of uric acid had led this substance to be regarded as playing a secondary part in the pathology of gout and its excess in the blood and deposition in the tissues as mere epi-phenomena of the disease, and he contrasted this view with the theory that uric acid even when held in solution in the body fluids exerted toxic properties and played a conspicuous part in the causation of gout. He regarded the presence of excess of uric acid in the blood as an established fact. This excess might possibly be due to over-production the result of tissue metabolism or of excessive ingestion of nucleins or purin substances into the alimentary canal. Over-production should, given normal kidneys, result in increased excretion, but such had never, except during the later stages of an acute case, been demonstrated in gouty individuals. Another explanation of the excess would be diminished destruction of uric acid in the organism, while the theory that the excess was due to the synthetic production of uric acid by the kidneys themselves required the assumption of a backward secretion from the kidneys to the blood for its acceptance. Dr. Garrod regarded with most favour the view that the excess in the blood was due to deficient excretion of uric acid by the kidneys, for it did not necessarily follow that an accumulation due to defective excretion involved a daily output below the normal level, and he pointed out that the consequent retention might either be due to defect of the kidneys which would at once remove gout from the category of metabolic disorders, or to something unusual in the form or combination in which uric acid was presented to the kidneys for excretion. Inborn metabolic instability and heredity and other factors bearing on gout were briefly discussed and Dr. Garrod referred to the result of the microscopical examination of the kidneys of all cases in which uratic deposits were present in the toe-joints appearing in the post-mortem room at St. Bartholomew's Hospital during one year, which showed that more or less interstitial change was present in all; on the other hand, many patients with chronic interstitial nephritis had no deposit in their toe-joints. A promising line for investigation was suggested in regard to the combination in which uric acid existed in the blood of the gouty and the organic compounds of uric acid with, for instance, nucleic acid were mentioned, and it was emphasised that it was as crystalline sodium biurate that uric acid was deposited in the tissues. The suggestion was also thrown out that the articular lesions and uric acid deposits were largely determined by local conditions, such as previous injury.

Dr. W. RINGROSE GORE (Llandrindod Wells) then read a communication on

The Pathology of Gout,

in which he stated that he considered the position of uric acid in gout as a minor one, for among other points the actual amount of uric acid in the blood in gout was in many cases small, in some it was absent, and in very few (if any) reached the amount often present in leukæmia. He considered that the symptoms of gout were undoubtedly toxic in character and due to a toxin circulating in the blood. Digressing to trace briefly the changes taking place in the articular affections of gout he discussed the source of the toxin responsible for the disease and dismissing the possibility of the production of toxin by bacteria actually in the tissues, elaborated the theory that the disease was due to the absorption of toxins produced within the digestive canal by some, at present unknown, specific bacillus which was a normal inhabitant of the intestinal canal; that individuals who possessed what was termed "unstable intestinal secretion," either hereditary or acquired, were prone to gout; and that each attack left an increased tendency to intestinal change which might in aggravated cases become permanent.

Dr. W. J. SMITH JEROME (Oxford) read a brief communication on the subject of

Spontaneous Precipitation of Uric Acid in the Urine,

in which he described comparative experiments upon a gouty individual and a healthy one which showed that uric acid precipitation was controlled by the food supply He then considered briefly the nature of the process concerned in precipitation, and after discussing the solvent powers of solutions of dibasic and monobasic phosphate salts respectively upon uric acid summarised the factors concerned in precipitation as (1) the proportion of acid to the base, (2) the percentage of uric acid, (3) the ratio of uric acid to dibasic phosphate , and (4) the ratio of monobasic to dibasic phosphate

Dr I **WALKER HALL** (Manchester) read a paper on

Variations in the Excreta in Gout

He pointed out the need for the recognition of variations in the excreta rather than permanent alterations Uric acid was to be regarded as a symptom not a cause of the disease Its varying changes offered some hope of ascertaining its origin Experimental variations had been produced in healthy as well as in gouty individuals by the administration of sodium salicylate and the production of constipation and in these instances changes in the uric acid output appeared to occur quite independently of cell destruction After stating the variations of nitrogen proteid and fat which occur in gouty individuals and enumerating the sources of endogenous uric acid and purins Dr Hall described some experiments conducted upon vegetarians and upon gouty patients In each case he had obtained an increased output of endogenous purins after the administration of sodium salicylate Similar results occurred during constipation both in normal and gouty individuals There was no concurrent evidence of increased cell destruction in the body and it seemed possible that the increased output was due to a decreased oxidation of the moiety of uric acid which is normally broken down to urea In some cases of gout the endogenous purins gradually decreased with the progress of the disease, although the exogenous purins were fairly well metabolised throughout The quantity of exogenous purins not excreted within 24 hours was very slight These facts suggested some alteration in the construction and affinities of the endogenous purins as contrasted with the normal properties of the exogenous purins The deposition of urates in the gouty tissues might be reasonably explained by these altered affinities or by the combination of urates and purins with abnormal albuminous substances In gout both exogenous and endogenous purins were in excess in the tissues and produced marked alterations in the lymph flow Dr Hall emphasised the need for a collective investigation upon gout in order to accumulate a large number of facts for further guidance and deprecated the tendency to form hypotheses upon insufficient evidence If further experiments confirmed their power to vary the constituents of the excreta they should soon obtain clearer light upon the etiology of gouty processes

A short discussion ensued on some of the points raised by the previous papers on Gout in which Mrs E L **WALKER DUNBAR** (Bristol) Dr J **HADDON** (Hawick) and Dr **GORE** took part

OPHTHALMOLOGY

FRIDAY JULY 29TH

Keratitis Profunda

In opening a discussion on this subject Mr W T **HOLMES SPICER** (London) said that the cases which he now brought under review were the accumulation of the past six years they were not great in number since the affection was comparatively rare They included only those continuously
watched [illegible] cessity
owing to on the
was in
entity and not merely a variety
all the 54 cases there was no
or acquired 34 cases occurred
he difference might be due to the
greater liability of men to injury and to devotion to alcohol The average age of incidence was 40 years Three fourths of the cases were associated with alcoholic excess especially in beer, with gout rheumatism and intestinal sepsis, whilst the remainder were connected with pyorrhoea alveolaris sciatica, dysentery, and pregnancy It was noticeable that many subjects were prematurely old In seven cases the onset followed injury from blows abrasion or foreign bodies The average duration of the attack was three months, the slightest lasted only three weeks, and the worst 12 months As a rule prognosis for vision was good The condition was characterised by a vascular ingrowth never amounting to a salmon patch, with a progressive opacity of the cornea In 25 cases the opacity occurred as a central disc, a grey patch in the deepest part of the cornea occasionally less dense in the centre than at the rim , in 22 it occurred as a conical opacity advancing from the periphery to the centre An almost constant feature was a striated keratitis, a radial marking from centre to periphery in the disc form, and a marginal finger like marking pointing to the centre in the conical form The lines were slightly uneven, sometimes crossing, rarely of double contour This striation was the earliest symptom of the disease it tended to be obscured by the advance of the opacity The opacity was either uniform or seen to be formed by the fusion of a number of maculæ soft, smooth edged and grey coloured features which distinguished them from the deposits of keratitis punctata Keratitis punctata was noted in 21 cases only , he had been inclined to consider the conjunction of keratitis punctata as a means of classification but later experience showed that the irregularity of its presence and onset in either form of the disease was an indication of severity rather than variety Iritis occurred in only 14 cases , in a very few there was subsequent sectorial atrophy of the iris Tension was increased in only four cases No fundus changes could be detected even at the extreme periphery although he had been prepared to find some , it was possible that any changes existing were so far forward as to be out of the range of the ophthalmoscope The surface of the cornea was roughened like to an orange rind sometimes bullæ formed which on rupture suggested a superficial ulceration In certain cases fluorescin instilled into the conjunctival sac was absorbed and stained the posterior corneal endothelium which was seen as a spotted green layer below the nebulæ The essential pathological condition he considered to be an œdema of the cornea , evidences of this were to be found in the bullæ of the surface and in the wrinkling of Descemet's membrane producing the striæ These were probably sequelæ to the altered condition of the posterior corneal endothelium which being shed in places, indicated by the deep staining reaction allowed the passage of fluid into the proper substance of the cornea Wagenmann in 1890 found that section of the long ciliary arteries produced partial opacity of the cornea with changes in the posterior endothelium and vascularisation of the cornea Koster ligatured the venæ vorticosæ, obtaining a similar parenchymatous keratitis Von Hippel combining these experimental operations was able to observe the early changes in the endothelium of the posterior corneal layers It was probable in the light of these experiments that the clinical picture detailed was due to vascular changes and that the variations in the forms observed were the result of a difference in the vessels affected The treatment was mainly general and dietetic—abstinence from alcohol, the relief of constipation and the imbibition of much bland fluid Mercury had no specific action Atropine to the eye and exclusion of light were of value Neither iridectomy nor peritomy was of use Subconjunctival injections of cyanide of mercury or of simple saline solution had no effect save that they were actually harmful in acute conditions

Mr **HENRY POWER** (London) remarked on the value of the signs obtained by the use of fluorescin which had no been in use in his day He had witnessed cases which he believed to be of the nature described in neglected and ill treated children and following on abrasions in women exhausted by long suckling and in harvesters He strongly urged the hopefulness of corneal conditions Opacities which practically excluded vision for long periods would not infrequently clear up in a marvellous fashion

Dr **CYRIL WALKER** (Bristol) said that his experience indicated that these erratic forms of keratitis were much more frequent in the west country than in London He thought it was not always easy to distinguish them from interstitial keratitis , indeed, he was inclined to doubt their being a distinct clinical entity He had also noted cases of recurrence at intervals from four months to two years Regularity and simplicity of diet he urged as a main factor in their treatment

Mr F M **GRANGER** (Chester) had observed such cases more frequently in women than in men and at a rather earlier average age The lesions were rather of the discrete macular form He had found the administration of dionine of much value

Dr. Koller (New York) remarked on the warnings commonly given against the simultaneous use of iodides internally and mercury externally; doubtless the warning had a general value but in some cases he had witnessed great improvements with this medication. Dionine he also thought of use.

Dr. A. Hill Griffith (Manchester) found a great difficulty in distinguishing these cases from the milder interstitial forms. He asked if anæsthesia of the cornea and anterior hyalitis, as indicated by dust-like opacities in the vitreous, had been noted.

Dr. G. Mackay (Edinburgh) had hitherto restricted the diagnosis to cases in which keratitis punctata was present, but he had recently seen some cases in which this symptom was absent.

Mr. Spicer, in reply, said that he was inclined to consider the cases in children described by Mr. Power as kerato-malacia. He thought the later age of the affection he described and the rarity of a simultaneous affection of the two eyes differentiated it from the commoner interstitial keratitis. He had noted recurrence but it was rare. He definitely excluded all cases in which anæsthesia of the cornea was present, since he believed these belonged to a neuro-paralytic group rather than to a vascular group such as these. He had remarked on his inability to find any indications of uveal inflammation, yet he was not without expectation that it would be ultimately noted.

Dr. Koller described his

Method of using Cocaine by Subconjunctival Injection for Anæsthetising the Eyeball for Cataract or other Operation.

The conjunctiva was rendered anæsthetic by the usual instillation, then two or three minims of a 5 per cent. solution were injected subconjunctivally at a point remote from the site of the intended section. Injection into the episcleral tissue was objectionable owing to the consequent œdema. In glaucomatous cases he combined the injection with eserine. By this means the iris was rendered completely insensible and manipulation was facilitated.

The President (Mr. R. W. Doyne, Oxford), Mr. Spicer, and Dr. Griffith asked questions as to the procedure, to which Dr. Koller replied.

Dr. Lucien Howe (Buffalo, N.Y.) described his researches on

The Time required for a Normal Eye to swing Laterally through a Given Arc.

The determinations were made in a simple manner by photographing simultaneously the movement of a beam of light projected upon the cornea and of a beam from a vibrating fork. By means of a series of photographs he demonstrated the rapidity and equality of the movements in the healthy eye as compared with those of eyes in paresis or other muscular defect.

The President congratulated Dr. Howe on the exquisite simplicity of his methods, the more so as he had himself spent much time and labour on similar experiments but with much more complicated apparatus, the use and results of which he had demonstrated to the section the previous afternoon. Dr. Howe's methods were applicable by anyone with a reasonable anticipation of success.

Dr. A. McGillivray (Dundee) asked whether Dr. Howe had investigated the altered mobility of the eye after such operations as tenotomy and of advancement; he thought the method might elicit some information of the different values of these operations.

Dr. Griffith said that he would like to see the instability of the eye movements in acute alcoholism investigated by the method.

Dr. S. J. Taylor (Norwich) was curious as to the results in nystagmus.

Dr. Howe replied.

Mr. W. W. Griffin (Brighton) exhibited

A Modified Bowman Suction Apparatus for the Removal of Lens Matter in Cataract Extraction.

The feature of the instrument was the automatic withdrawal of the piston by the action of a spiral spring wound round the piston shaft.

Professor Hirschberg (Berlin) said that the operation of suction was almost as old as that of couching. It was practised by the Persians and Arabians certainly as early as A.D. 900. It had been revived in some measure in recent years, but he thought that it was as obsolete as couching.

Dr. James Hinshelwood (Glasgow) read notes of a case of

Pure Word-blindness with Right Homonymous Hemianopsia,

and demonstrated the pathological conditions by beautiful photographs prepared by Dr. MacPhail and Dr. A. R. Ferguson of the pathological department of the University of Glasgow. The patient had completely lost the capacity of understanding word symbols, though he retained the knowledge of figures and could write to dictation. Speech and general memory were good. On death, nine years later, much atheroma of the basal arteries and complete destruction of the left occipital lobe below the calcarine fissure were found. The cuneus and angular gyrus were healthy.

Dr. Hinshelwood also read a paper on

Word-blindness in Children.

These cases were, he believed, rare and not commonly recognised by ophthalmic surgeons. They were characterised by good vision for all purposes except to word symbols. Very careful and laborious individual teaching resulted in the gaining of the faculty in some slight degree.

The President remarked that he did not think the condition so rarely recognised; he had seen some few cases.

Mr. N. Bishop Harman (London) said that he was surprised at Dr. Hinshelwood's belief that the condition was so rarely recognised by surgeons. In London educational work it had long been known, and the affected children were provided with instruction fitted to them in the admirable "Special Schools" of the London Board (now County Council) schools. In the recent report of the work of the medical department of the London Education Committee by Dr. James Kerr, details were given of the condition and progress of several such cases, with reproductions of their performances in writing and figuring. They had so far appreciated the essential inability of these children to learn word-symbols that they no longer sought to teach them the unattainable, but aimed at developing such faculties as they possessed, with the result that some of the defective subjects were able to earn decent wages in after life. He was pleased to find that at least in one department the much maligned English educational system was ahead of the Scottish.

Mr. Sydney Stephenson (London) said that such cases were not uncommon; boys were more often affected than girls. He had recorded two amongst the many published.

The President and Mr. G. E. Wherry (Cambridge) remarked upon features of the cases of the acquired affection.

Dr. Hinshelwood replied.

Dr. George Carpenter (London) read notes of

A Case of Retinitis in a Child with Large White Kidneys.

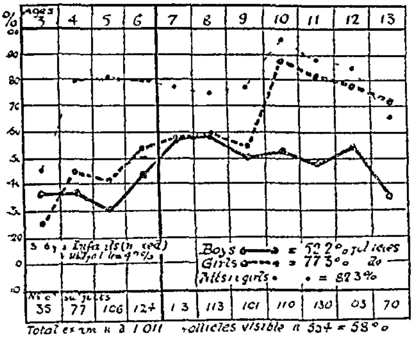
The case was *apropos* of the paper read last year before the Association by Mr. E. Nettleship who commented on the rarity of the conjunction. This case was the only one found during 20 years' observation. The neuro-retinitis was gross and long continued; the diagnosis of kidney affection was made by the condition of the urine and confirmed by the necropsy.

Mr. Bishop Harman read a paper on

The Lymph Follicles in Healthy Conjunctivæ.

The presence of lymph follicles in the palpebral conjunctiva of such a size as to be visible to the naked eye was not infrequently a source of perplexity. In the diagnosis of cases of conjunctivitis it might be questioned, What relation did the follicles bear to the existing inflammation in the case under examination? Were they antecedent and therefore only coincident? Did they indicate some grave tendency, say to trachoma? Or it might be a casual visitor to a school chanced to light on a pupil whose conjunctiva showed many visible follicles and there crowd upon his memory the similitudes of "sago grains," "frog's spawn," and the like to dire conditions of ophthalmia which he had heard at some congress and a storm was raised in the school. Anatomically considered they were minute collections of lymph cells scattered over the conjunctiva immediately beneath the epithelium; they were fairly plentiful in the lower lid, in large numbers in the retrotarsal folds, very sparsely scattered in the conjunctiva which was so firmly attached to the tarsal plate of the upper lid, but were fairly numerous at the angles of this lid; they were absent over the ocular conjunctiva. In structure they did not differ from the many other solitary follicles scattered throughout the mucous membranes of the body. Greeff found that they were visible in 70 per cent. of school children and Delbès in 49 per cent.

of males and in 52 per cent of females In June of last year Mr Harman made a systematic examination of over 1000 children in a London board school situated in the north east district The parents of the children were working folk, the children in the majority were well and cleanly clothed Of 1011 children 554, or 58 per cent, had visible follicles In 342 infants of ages from three to six years 144, or 42 per cent, showed follicles In 341 boys from seven to 13 years of age 178, or 52 2 per cent and in 328 girls of the same ages 232, or 77 3 per cent the follicles were visible The girls thus exhibited follicles in much greater proportion than the boys When the results of the examination of the conditions in girls and boys were plotted down on a chart for each year of life (see chart) it was noted that between the ages of three and nine years the curve of incidence for boys and girls was almost the same, the difference came in suddenly and markedly in the tenth year and persisted for the remaining years of school life, a separation averaging about 30 per cent At the time of this examination he had noted the condition of the hair of the head of the girls These figures showed a similar curve to that of the follicles in the girls There was a fair average level between the ages of four and nine years, then a sudden rise of 20 per cent in the tenth year followed by a slow decline in the subsequent years Inquiries showed that at about the age of ten years the girls were expected to take up their share of the home duties With this responsibility came the liberty to look after themselves hence the increase of the nits from neglect of the person, and with this an increase of the lymphatic structures indicative of diminished good health When personal pride came in as a factor the person became cleaner, the curve of nits fell and with better cleanliness and health the curve of the follicles also declined "Folliculitis" or any term that would indicate the existence of an obvious inflammation had been avoided, indeed, there were no signs of inflammation of the conjunctiva of any sort There were some few cases in which the follicles were gross in their size, yet there were no signs of inflammation Recently extreme cases of this kind had been seen at hospital Two were Jewish emigrants desirous of proceeding to America but who had been inhibited by the shipping agent, the third was an English lad In all these cases the follicles were as large and prominent as they well could be, they had a normal distribution, the lower folds were filled with row on row of large pale oval bodies each about 1 5 by 3 millimetres the upper fold of transition and the angles were similarly crowded, and a few were dotted here and there over the upper tarsus In the two youngest patients there were
the upper ocular c
epithelium of the
quite normal in appe—
could be seen passing over them in their normal course Of symptoms associated with the eye condition there were none



The incidence of visible follicles in the conjunctivæ of healthy school children

the lids to the ocular conjunctiva The other cases were treated by the gentlest expression possible and with blue stone, in a month from the time of the expression the conjunctivæ were normal in appearance, there was no scarring save for the fine line which marked the site of a portion excised for histological examination One of these latter cases left for America and since he had never reappeared Mr Harman judged that he had passed the immigration officers, but the boy who was treated by "brossage could never get to America, his scarred conjunctiva told a tale which would bar him at every port Sections of the mucosa taken from *two cases showed an absolutely normal conjunctiva, save for* the monstrous size of the follicles The epithelium was normal, the submucosa was delicate and free from signs of inflammation the follicles, although monstrous in size formed exactly to the anatomy of a solitary follicle, as seen, say, in the gut, the cells were soft and round, packed in proper zones and there was no excess in the endothelial stroma, *in looking at the sections the remark of Brush, the* discoverer of the follicles of the conjunctiva, that they and the follicles in Peyer s patches were similar was irresistibly brought to mind The feature of these conjunctivæ was an immense increase of the lymph cells of local origin an abnormal development or rather, accumulation of cells in the local follicles which had failed to pass in due course into *the lymph stream and a lymph follicle stasis* There was no leucocytosis of external origin None of these features conformed in any way to trachoma, which was characterised by a marked hyperplasia of the endothelial stroma of the follicles and general adenoid tissue of the lids Such sections could have been obtained from most of the 563 children in the school of 1011 If the condition were, as was held by some trachoma then all these children were condemned to the diagnosis, a conclusion which was absurd Such conditions of the lymph follicles were not contagious, there was no danger of these cases setting up a vicious condition of the same or any other order in their neighbours, the subject of the disorder was, however, liable in the unhealthy and stagnant state of the local lymph circulation and general ill health to fall a victim to any virus that might be about with the result that the contraction of a simple catarrh that would pass almost unnoticed in another would in such a case look serious and receive the formidable name of follicular conjunctivitis" and the child be excluded from school as dangerous He examined bacteriologically 12 consecutive cases of this order In seven the brief history of acute symptoms indicated a catarrh supervening on follicular hypertrophy the determining causes of the inflammation were found to be Koch-Weeks s bacillus twice, Morax bacillus once, steptococcus once and staphylococci thrice All the cases made a rapid recovery Of five, in which the diagnosis was complicated by a somewhat lengthy history and some tendency to papillary exaggeration, three were finally diagnosed as simple conjunctivitis, one proved to be trachoma, and one remained in doubt The conclusion from this evidence was that *a diagnosis of* follicular conjunctivitis was defective, it did not take into consideration the frequency with which enlarged follicles were seen in healthy subjects, it gave no indication whether the case was to be taken *to be a simple catarrh* occurring in such a subject or whether the examiner conceived it to be something of a more serious nature

The PRESIDENT and Dr ADOLPH BRONNER (Bradford) asked questions to which Mr HARMAN replied

Dr BURNHAM (Toronto) read a paper on

The Combined Treatment in Disease of the Eye, especially in that of the Uveal Tract

This combined treatment of the internal administration of mercury and the iodide of potassium associated with the hypodermic injection of pilocarpine he had practised for 15 years He described two cases of sympathetic ophthalmia, one in which the acute attacks were stayed and after nine *months* vision improved from perception of light to $\frac{6}{18}$ The second case, of similar order, in an active state but of longer duration had only perception of light minus tension, and occluded pupil Under the combined treatment for eight months the eye became so quiet that he felt justified in removing the lens with a result that visual acuity reached [illegible] and J 1 No relapses had occurred in either case after several years In a case of chronic articular rheumatism with transverse calcareous band useful vision was obtained, one of acquired syphilitic cyclitis with occluded pupils and qualitative vision obtained in one and a half years $\frac{20}{40}$ vision in one eye and $\frac{20}{20}$ in the other. In some severe types of hypopyon kerato-iritis and in old sclero-keratitis the clearing of nebulæ was marked; these were cases in which all other measures had failed. He considered the combination of drugs which he had used peculiarly adapted to promote vigorous tissue change.

Dr. BRONNER read

Notes on a Case of Thrombosis of the Cavernous Sinus due to Empyema of the Sphenoidal Sinus.

Cases of thrombosis of the cavernous sinus were not very common. This case, occurring in a slightly anæmic but otherwise healthy girl, was remarkable in that it was impossible to account for the origin of the thrombosis during life. The nares were healthy. There had been no abnormal discharge from the nares. There had been some severe headache and pain but no sickness; this was followed in a few days by slight swelling of the right eyelids, chemosis, and well-marked proptosis. There was no strabismus but movements of the eye were limited. The fundus was normal. The symptoms gradually grew worse. The temperature varied between 99° and 103° F. A rigor, with a temperature of 104·6° and profuse perspiration, occurred despite treatment with calomel and local leeching. Cerebration was slightly impaired, but questions were answered correctly though slowly. After a fortnight the symptoms diminished and swelling of the retinal veins of the right eye was noted. On a relapse antistreptococcic serum was injected several times without benefit. The temperature rose to 105° and 106° almost daily and there were several slight rigors and the left jugular vein became inflamed. Vision of both eyes was fairly good considering the patient's mental condition. On the eighteenth day offensive diarrhœa set in and continued until death on the thirtieth day. Post mortem both cavernous sinuses were found to be filled with purulent thrombus. The left lateral and petrosal sinuses were gangrenous, the longitudinal sinus being filled with clot. There was some pus (sweet) at the apex of both orbits. Both sphenoidal sinuses were full of pus and granulation tissue; the septum was practically destroyed. The ethmoidal and frontal cells were apparently not affected. The empyema of the sphenoidal sinus doubtless caused the thrombosis of the cavernous sinus. This was an exceedingly rare occurrence. The absence of disease in the sphenoidal sinus, the late and slight affection of the optic disc and retinal veins without retinal hæmorrhages, and the absence of cerebral irritation and vomiting were remarkable. Operation was proposed but was not consented to. Germain[1] had collected 182 cases of thrombosis of the cavernous sinus with 16 recoveries. 134 necropsies were recorded. In 31 cases one sinus only was affected; in all the others both were affected.

The proceedings closed with a vote of thanks to the President, Vice-Presidents, and secretaries, proposed by Mr. POWER and seconded by Dr. HOWE.

Attached to this section was an exhibition of surgical and x-ray instruments and a pathological museum. Experiments relating to Colour Vision were demonstrated by Dr. G. J. BURCH, F.R.S.; on Colour Blindness, by Dr. F. W. EDRIDGE-GREEN; and on Colour Photography, by Miss ACLAND. Instruments were exhibited by Mr. A. MCGILLIVRAY, Dr. E. MADDOX, Mr. S. STEPHENSON, Dr. K. GROSSMANN, and Mr. ANDREW LITTLE. A large series of pathological specimens and drawings were shown by the PRESIDENT, Mr. W. H. H. JESSOP, Mr. STEPHENSON, Mr. VICTOR MILLER, Mr. OGILVIE, and Professor M. M. MCHARDY; and Demonstrations on the Variability of the Fields of Vision with different illumination in cases of Tobacco Amblyopia were given by Mr. N. BISHOP HARMAN.

THE PATHOLOGICAL MUSEUM.

IT was at a meeting of the British Medical Association at Oxford in 1868 that the annual museum of the Association was first initiated and it is at Oxford in 1904 that the museum has been reinstalled in its rightful position. The idea of the founders was that it should form a means of bringing the mass of the profession into touch with recent pathological methods and data, especially such as had some bearing upon the practical work of the profession, and that these annual exhibitions should summarise, as it were, the work done in pathology during the preceding year from a clinical, anatomical, and laboratory standpoint. The advances made in pathology and the new light thus shed upon the science of medicine during the 36 years have been extraordinary. But the annual pathological exhibition of the Association has not, as has been pointed out on more than one occasion in these columns, kept pace with the advances in the science of medicine. This year, however, the museum has once more taken its proper place, and the wealth of material collected in two large rooms, conveniently adjacent to the pathological and anatomical sections of the Association, affords examples of nearly all the departments in which recent researches have been made. Indeed, so handsome was the response to invitations this year that the collection in the museum proper was a trifle overcrowded and there were also two overflow exhibitions. The excellent collection of ophthalmological specimens was housed in the junior common room of Keble College and the section of dermatology arranged specimens supplementary to those shown in the Pathological Museum at the meeting-place of the section.

Tropical diseases were well represented. In this department of medicine many curious names unheard of before are now becoming quite familiar even to those who spend their days in Great Britain. The trypanosoma has occupied a good deal of attention lately. It is a flagellated protozoon or worm-like organism found free in the blood and moving with a screw-like progress, blunt at one end, with a flagellum at the other, its length including the flagellum being only about 18μ. It produces a disease called trypanosomiasis, long known in West Africa, characterised by irregular pyrexia, erythematous rashes, and enlargement of the liver and spleen. It has more recently been found in the blood of patients suffering from the disease known as "sleeping sickness," a disease in which polyadenitis is a prominent feature. When the trypanosoma gains access to the cerebro-spinal fluid (although it may have previously existed for years in the blood) the patient develops the narcotic symptoms of sleeping sickness. Interesting specimens illustrating the life history of the trypanosoma and the pathology of "sleeping sickness" and kala-azar were exhibited by Dr. David N. Nabarro (London) and Dr. G. C. Low (London) respectively. Kala-azar is a disease in which enlargement of the spleen occurs. It is met with in China and other malarial districts and was for a long time confused with malarial fever. Certain bodies have now been found in this disease, known after their discoverers as Leishman-Donovan bodies, which are believed to have some relation to the trypanosoma, though what that relationship is still remains to be worked out. The nature of these remarkable bodies has been much debated and only quite recently a telegram, dated June 29th, has been received from Captain Leonard Rogers, I.M.S., stating that he had succeeded in developing the trypanosoma from cultures of the Leishman-Donovan bodies. It would seem probable, therefore, that the trypanosoma in its various phases of evolution is responsible not only for the condition known as trypanosomiasis but also for "sleeping sickness" and for kala-azar. Excellent photographs and sketches of ankylostomiasis and bilharziasis (two grave forms of anæmia resulting from their respective parasites) were exhibited by Dr. F. M. Sandwith (Cairo); internal lesions produced by ankylostoma by Dr. M. Armand Ruffer (Egypt); and specimens of "kra-kra" or "craw-craw" by Mr. J. Dencer Whittles (Birmingham). Craw-craw is a papulo-pustular eruption somewhat resembling scabies and occurring mainly among the inhabitants of South Africa. In connexion with the last-named disease a photo-micrograph was exhibited of the nematode worm (filaria perstans) causing this disease, which had been found in the blood of a female patient resident at Tenby, South Wales, in whom infection had taken place at Birmingham whilst on a visit in February, 1903. It would have been interesting to know the source and mode of infection.

In neurology the scientific worker requires to be patient and to be content to devote much time with the prospect of what appears to be a very small return. The microscopical sections exhibited by Dr. F. Griffith (Liverpool) and Dr. W. B. Warrington (Liverpool) illustrated the truth of this. These sections revealed the changes which take place in the posterior spinal ganglia after section of their various connexions. They represented a good deal of laborious work. We know that the cells of the spinal ganglia have some special relation with the sympathetic system and a marvellous but ill-defined trophic action on the skin and other tissues. We know, for instance, that the lesion of herpes is situated in these ganglia. Disorders of the sympathetic and vasomotor systems have received a good deal of attention lately from a clinical standpoint, and these structures would well repay a careful anatomical and physiological study in the laboratory. A knowledge, for instance, of the control which sympathetic system would be of lows (Lancaster) and Dr. David nine microscopic specimens prepared by Marchi's method showing acute lesions of the posterior columns of the spinal cord Fine bacilli were seen within the cell bodies and in their immediate neighbourhood. These observations are in keeping with the researches of Dr James Taylor and others into the now well-known toxic origin of spinal sclerosis Dr J S Collier (London) and Dr D F. Buzzard (London) exhibited specimens and photographs taken from four cases of congenital diplegia in three of which certain congenital deficiencies in the nervous system were discovered There is no doubt that some cases of congenital diplegia are due to injuries at birth but these specimens add further proof that a good many of them are dependent on abnormal or arrested development of the hemispheres and other congenital deficiencies in the nervous system. Incidentally Dr Collier's method of staining nerve cells (which has been described in the *Review of Neurology and Pathology*) was illustrated

---

[1] Boston Medical Journal, May 1st, 1902.

The pathology of cancer was well illustrated by observers holding diverse views Dr. E. H Bashford (London) and Mr J. A. Murray (London) exhibited specimens illustrating the preliminary changes which take place in the nucleus and in the chromatin of the nucleus in the development of cancer, the cell of the somatic and heterotype mitoses in trout, and the cell conjugation in transplanted mouse tumour, changes which these gentlemen regard as essential and as pointing to the origin of cancer in a "physiological rest" or residue of embryonic tissue rather than the result of a protozoic process Dr. W Ford Robertson (Edinburgh) and Mr. Henry Wade (Edinburgh) on the other hand exhibited specimens illustrating the development of plasmodia in the turnip in the disease called "finger and toe" These observers regard the disease as a protozoic process and if, as they maintain, this plasmodium in the turnip is identical in the stages of its growth with the protozoon found in cancer their results will prove extremely interesting. Fuller details of their views were given in the demonstrations at the Vice-Chancellor's conversazione and are reported in THE LANCET of August 13th, p 467

The pathology of acute rheumatism was illustrated by some observations made by Dr W Vernon Shaw (Oxford) and Dr J. M. Beattie (Edinburgh), both of whom exhibited the lesions produced by artificial inoculation of acute rheumatism in animals The results arrived at by these observers fully bear out the statements of Dr F J Poynton and Dr Alexander Paine and go far to show that acute rheumatism is due to a specific microbe. The diplococcus has been isolated, the inoculation of cultures has produced the same disease in animals, from whom again the characteristic diplococcus has been collected—in short, all the classical tests of an organism being the specific cause of a disease, as required by Koch, have been fulfilled

Cardio- Dr G A. Gib of specimen ral of which were of tuberculous origin One of these had been diagnosed during life chiefly by the paradoxical pulse, a pulse intermitting every fourth beat in correspondence with the respiratory rhythm Professor T Clifford Allbutt (Cambridge) exhibited a specimen of chronic aortic stenosis occurring in an elderly man who had suffered for the last two or three years of life from typical attacks of Stokes-Adams' disease, during which the heart beats had numbered only eight to 12 per minute A large number of very careful drawings of the microscopic changes in the liver in mitral stenosis and other cardiac conditions, accompanied by specimens of the liver to show the naked-eye appearance, were exhibited by Dr R N. Salaman (London). Several important contributions have recently been made to the subject of arterial disease. Unfortunately considerable confusion exists as to the meaning of the term atheroma, which in Germany appears to be regarded as identical with arterial sclerosis Many English observers, like Dr W Russell,[2] regard atheroma as a totally distinct affection The specimens and photo-micrographs exhibited by Dr. T D. Savill (London) go to confirm this view. Among other cases he had investigated that of a woman, aged 100 years, who had presented extremely profuse atheroma not only in the larger arteries (which is usual in old people) but even in the ultimate ramifications of the smallest vessels She had died from hypostatic congestion of the lungs and had never exhibited circulatory symptoms of any kind during life Others of Dr Savill's specimens illustrated the anatomical condition which he has described as arterial hypermyotrophy[3] and the subsequent degenerations which take place in the tunica media—i e, the muscular and most important coat of the arteries

Interesting specimens bearing on gynæcology, too numerous for us to notice in full, formed part of the museum. Dr James Ritchie (Oxford) and several others exhibited specimens of chorion epithelioma, a disease due to the inclusion of the trophoblast in a part of the body distant from that in which it is usually found. Mr Cuhtbert Lockyer's series were very interesting, especially one of them which showed how a fibromyoma may become sarcomatous and malignant Dr. Nathan Raw (Liverpool) showed a number of specimens of tuberculous disease which illustrated his paper on Human and Bovine Tuberculosis delivered in the Section of Medicine.

In the department of surgery there were also many interesting exhibits We have rarely seen anything more perfect of their kind than Mr. W. G. Richardson's (Newcastle-on-Tyne) series of specimens illustrating the anatomy, comparative anatomy, development, and pathology of the prostate and male genitalia Removal of the prostate gland is coming more and more into vogue with surgeons, and these specimens, together with those exhibited by Mr. John T Hewetson (Birmingham) and Mr P. J Freyer (London) who advocates the suprapubic method, were particularly opportune. A series of very instructive radiographs, illustrating Colles's fracture and congenital dislocation of the hip treated by Lorenz's method, were shown by Mr Robert Jones (Liverpool) and Dr David Morgan (Liverpool), and a great number of other diseases of the bones and joints were illustrated These specimens would have well give to the were avail Tyne) exhibited a life sized model, together with photographs illustrating the effects of lightning Two men were seated under a tree and the lightning swept from the tree to the ground between the men, throwing them many yards apart It tore the boot and clothes of one of them into ribbons down the right side Yet, if we may judge by the photographs, the patient completely recovered Another extraordinary case was that of a young man in whom four inches of a hay fork became imbedded in the superior maxilla and remained there for two years. Another specimen exhibited the effects of a tooth-plate which had perforated through the œsophagus into the left bronchus and which was removed by posterior œsophagotomy Specimens illustrative of the absorption of ligatures were exhibited by Sir William Macewen (Glasgow), By various methods of preparation a ligature can be made to undergo absorption in the wound at the end of three, four, five, or more days, according to the requirements of the case The wound is dressed simply with a strip of gauze painted over with collodion which can be peeled off on the desired day bringing with it the unabsorbed part of the ligatures At these annual exhibitions there is generally a collection of appendices removed by operation Dr. G Grey Turner (Newcastle-on-Tyne) and Dr W Blair Bell (Liverpool) exhibited a particularly interesting series of specimens removed during the preceding year or two which had been studied and labeled with extreme care Mr. F M. Caird (Edinburgh) showed fifty preparations to illustrate the surgery and pathology of the stomach, intestine, and kidney.

Several useful models were on view Mr H G Armstrong (Crowthorne) showed a "waistcoat pocket" albumin testing apparatus, Dr J Mackenzie (London) a sphygmograph and blood-pressure recording instruments, Dr. I. Walker Hall (Manchester) a purinometer for the clinical investigation of urinary purins, and Mr. C. W. Cathcart (Edinburgh) showed a cast illustrating an improved method for making papier-mâché casts of pathological specimens or dissections The facility with which these casts can be made should recommend them to those who wish to make their museums complete. The great usefulness of skiagraphy in medicine was proved by the excellent skiagraphs of acromegaly, chronic pulmonary osteo-arthropathy, and myositis ossificans exhibited by Dr. G. A. Gibson (Edinburgh), and those of early pulmonary tuberculosis, and pleural effusion shown by Dr. A. Stanley Green (Lincoln). The drawings and colour sketches were of unusual excellence. One of these, a case of facial ecchymosis and pigmentation occurring at the catamenial periods, afforded another example of the close association between the menses and the vaso-motor sympathetic system. Such cases should be investigated side by side with the *edème bleu* of Charcot and the angio-neurotic œdema which has lately been receiving attention. The investigation would be a difficult one, because it would necessitate a simultaneous study both of the sympathetic system and the peculiar qualities of blood at the time. A number of interesting specimens were exhibited to show the efficiency of the two, three, and four colour printing processes. Photography in colour and its methods were demonstrated and photo-micrography was shown in a high degree of perfection by Mr. Albert Norman (London) and Dr. W. A. P. Waters (Oxford).

[2] THE LANCET, June 1st, 1901, p 1519.

[3] Transactions of the Pathological Society of London, 1904

It has been impossible in the space at our disposal to notice more than a few of the leading examples in this excellent collection. We are glad to observe that the suggestion made in these columns last year, that short demonstrations on the museum specimens should be held from time to time, was carried out at the Oxford meeting. On Wednesday lantern demonstrations of colour photography were given by Mr. E. Sanger Shepherd and Mr. J. Hall Edwards; on Thursday, Dr. A. E. Wright demonstrated the preparation and use of the pipettes which he has introduced for bacteriological research, Dr. R. N. Salaman gave a demonstration of the reservoir action of the liver in cardiac disease, and Dr. Walker Hall demonstrated his purinometer; and on Friday Mr. C. W. Cathcart gave a lantern demonstration illustrating the gradation of malignancy in bone tumours. The number of visitors to the museum was one of the largest within our recollection. The interchange of views between members meeting from a distance and the discussion of the specimens, which were continuously carried on from the opening to the closing of the museum were of the most instructive kind. Such discussions added not only to the interest but to the scientific value of these gatherings. There is no doubt that the Pathological Museum was one of the most attractive features of this year's meeting of the Association, and Dr. James Ritchie, Dr. E. W. Ainley Walker (the secretary), and the committee are to be congratulated heartily on their unqualified success.

Looking Back.

FROM

THE LANCET, *SATURDAY*, AUGUST 19, 1826.

DIRECTIONS FOR THE USE OF THE STETHOSCOPE.[1]

Almost seven years have now elapsed since LAENNEC proposed mediate auscultation as a mode of exploring the diseases of the thoracic viscera: a period sufficient in this busy age of investigation to try the merits of any hypothesis; and to outlive such a probation is almost enough to ensure permanent popularity. After various trials with materials of different density, a perforated cylinder of moderately light wood has been found the most convenient; and what may appear at first in opposition to an axiom in physics, in the present case the most accurate conductor of sound. To this cylinder the name *stethoscope* has been given; a name which very well expresses its principal use. The stethoscope merited, and has now obtained the patronage of the majority of scientific practitioners, and up to the present time has had the rare fortune of being without one decided public opponent. It is employed almost universally in France, and extensively in Germany, but as yet not so frequently in this country as it deserves; we are therefore glad to find that Sir JAMES MACGREGOR has recently ordered the army surgeons to use it generally, and to report the results of their investigations.

The appointment of LAENNEC to La Charité gave to him and to the numerous students who attend his clinic from all parts of Europe, more frequent opportunities of studying auscultation, than they could have ever hoped for at the Necker Hospital; and it is to this circumstance we are principally indebted for the improved shape in which the present edition of his work has appeared.[*] We regret to say that his health is in a very precarious state; he is obliged to leave the clinic to the superintendence of others, and is gone into Britany, where he will pass the summer.

The first edition of Laennec's work has been translated into German, under the superintendence of Dr. FRORIEP, at Weimar, and into English by Dr. FORBES; it has also found its way into the Italian and Russian languages. The last edition of the valuable work of BERTIN,[*2] edited by his friend Bouillaud, on the diseases of the heart and large vessels, and the clinical reports published by LERMINIER and ANDRAL,[†] contain many facts illustrative of the use of the stethoscope. Dr. FORBES,[‡] also, in 1824, published a considerable number of cases observed at the Chichester Dispensary; but the greatest number of interesting facts has been collected by Dr. LOUIS of Paris, who during the past year has published a very respectable work on pulmonary consumption.[§] It is true that Andral has given a negative testimony against some of the signs said to be afforded by the stethoscope, but this is of no great weight, since Laennec had before admitted the existence of the same objections, under certain circumstances.

Many persons have inquired why Laennec has called it *mediate* auscultation; it is to distinguish it from *immediate* auscultation, or the direct application of the ear to the chest; a mode of examination with which the father of physic was so well acquainted, that he thought he could distinguish a serous from a purulent effusion in the thorax. "You will know by that," says he, "that the chest contains water and not pus, if by applying the ear for some time to the parietes, you hear a sound like to that of boiling vinegar."[‖] It is singular that the passage never arrested the attention of physicians so as to induce them to make any use of it; the commentators of Hippocrates passed over it as a matter of little consequence, and Laennec confesses that many years before the idea of mediate auscultation suggested itself, he had read the same passage without exciting any particular attention.

In the summer of 1816, Laennec was called to a young lady who presented the general symptoms of disease of the heart; the application of the hand to the chest, and percussion, afforded very little assistance, and immediate auscultation was interdicted by the sex and *embonpoint* of the patient. The recollection of the well known fact, that the tap of a pin at one end of a beam could be heard distinctly at the opposite end, induced him at the moment to avail himself of this acoustic phenomenon. He took a quire of paper, rolled it tightly together, applied one extremity over the region of the heart, and putting the ear to the other, was surprised to find that he could distinguish the pulsation of the heart in a more distinct manner than he could before do with the naked ear. Having hit upon the principle, he extended its application to the investigation of the various sounds produced in the chest by the respiration, the voice, and the accidental presence of fluids in the lungs, pleural sacs, and pericardium. He immediately commenced a series of observations at the Necker Hospital, which have afforded a large number of new and safe signs, easy to be understood for the most part, and calculated to make the diagnosis of almost all the diseases of the lungs, pleura, and heart, more circumstantial and certain than the surgical diagnostics established by the aid of the probe or the finger.

THE LANCET.

LONDON: SATURDAY, AUGUST 20, 1904.

Mr. Balfour on the New Theories of Matter.

IN his presidential address delivered before the British Association for the Advancement of Science at Cambridge, an abstract of which we publish this week, Mr. BALFOUR, with the candour and simplicity which have made him so engaging and forceful a personality, disclosed to his audience his personal views of the new theories of matter. The Prime Minister is not an original worker in the domain of science or an expert in laboratory procedure, but the reflections which the new theories of matter have suggested to his mind bespeak a profound observer as well as a close student of the work going on in many scientific fields. It will be remembered that Mr. BALFOUR'S illustrious uncle, the late Lord SALISBURY, who was president of the British Association at Oxford in 1894, delivered on that occasion a very able and remarkable address entitled "The Unsolved Riddles of Science." The lesson conveyed by Lord SALISBURY was that all around us there lie strong proofs of intelligent and benevolent design, but Mr. BALFOUR approaching a similar theme with a more vaguely philosophic equipment is not able to come to quite so concrete a conclusion. He has been tempted to review our ignorance rather than our science. There is a pessimistic tone throughout his address, for the achievements of past researches, despite their brilliance, would seem to suggest to him how hopeless it is to expect that the final clue to the central mystery will ever be found. Whilst admitting that the advances of each section of knowledge have been great the hope of understanding the origin and meaning of life is as far off to him as ever, and his lesson appears to be that human power and perception have limitations against which it is useless to struggle. The danger of such reflections is that they may tend to damp the praiseworthy enthusiasm of the investigator. They would do so were it not that the man who is in earnest is proud to win even "a small strip from the desert" and so to push forward the boundary of the oasis of knowledge in which we live. Let us at least have the joy of accumulating knowledge, though there may be no prospect of the last goal ever being reached. The beautiful peroration of an address delivered by Sir WILLIAM CROOKES on a similar occasion ran as follows: "Steadily, unflinchingly," he said, "we strive to pierce the inmost heart of nature, from what she is to reconstruct what she has been, and to prophesy what she yet shall be; veil after veil we have lifted and her face grows more beautiful, august, and wonderful with every barrier that is withdrawn." These are the sentiments which stimulate the true worker, and we regret any limitations being even theoretically set to our intellectual march forward.

The extraordinary stimulus given to our conceptions of the nature of matter by the discovery of radium and by a consideration of its marvellous properties was probably all the time in Mr. BALFOUR'S mind though throughout the address the subject was not mentioned. He, in common with many, has no doubt sustained something like a mental shock to learn that no longer must the atom be regarded as the smallest conceivable particle of matter but rather as a tiny cosmos in itself, swarming with electrified particles travelling freely in all directions, which particles or electrons may appear at one time as matter and at another time as force. "There are those," he said, "who regard gross matter, the matter of every-day experience, as the mere appearance of which electricity is the physical basis; who think that the elementary atom of the chemist, itself far beyond the limits of direct perception, is but a connected system of monads or sub-atoms which are not electrified matter but are electricity itself." Again: "Two centuries ago electricity seemed but a scientific toy. It is now thought by many to constitute the reality of which matter is but the sensible expression. It is but a century ago that the title of an ether to a place among the constituents of the universe was authentically established. It seems possible now that it may be the stuff out of which that universe is wholly built." With characteristic subtlety of phrase he adds that matter is not merely explained, but explained away, by assuming that the atom is now no more than the relatively vast theatre of operations in which minute monads perform their orderly evolutions, while the monads themselves are not regarded as units of matter but as units of electricity. Mr. BALFOUR next proceeded to show by a somewhat original line of reasoning how really unfitted man is, after all, to comprehend all around him in spite of his remarkable success in bringing wonderful phenomena to light. "It is certain," he said, "that our powers of sense perception and of calculation were fully developed ages before they were effectively employed in searching out the secrets of physical reality, for our discoveries in this field are the triumphs but of yesterday. The blind forces of natural selection, which so admirably simulate design when they are providing for a present need, possess no power of prevision and could never except by accident have endowed mankind, while in the making, with a physiological or mental outfit adapted to the higher physical investigations. So far as natural science can tell us every quality of sense or intellect which does not help us to fight, to eat, and to bring up children, is but a by-product of the qualities which do. Our organs of sense perception were not given us for purposes of research, nor was it to aid us in meting out the heavens or dividing the atom that our powers of calculation and analysis were evolved from the rudimentary instincts of the animal." Upon this exposition follows Mr. BALFOUR'S conclusion. It is, he thinks, due to these circumstances that the beliefs of all mankind about the material surroundings in which it dwells are not only imperfect but fundamentally wrong.

The gist of Mr. BALFOUR'S reflections suggested by the new theories of matter is contained in his forcible presentation of the case in the following sentences: "Extend the boundaries of knowledge as you may; draw how you will the picture of the universe; reduce its infinite variety to the modes of a single space-filling ether; retrace its history to the birth of existing atoms; show how under the pressure of gravitation they became concentrated into nebulæ, into suns, and all the host of heaven; how, at least in one small planet, they combined to form organic compounds; how organic compounds became living things; how living things, developing along many different lines, gave birth at last to one superior race; how from this race arose, after many ages, a learned handful who looked round on the world which thus blindly brought them into being and judged it and knew it for what it was—perform, I say, all this and though you may, indeed, have attained to science in nowise will you have attained to a self-sufficing system of beliefs." It would, indeed, be a remarkable consummation of the penetrative instincts of the human race if the fundamental truth should be so clearly revealed that it would be impossible for a sceptic to remain. We cannot, some would say we must not, expect so much; but the more, to use Mr. BALFOUR'S words, we attain to science the more chance is there of appreciating the wider and deeper lessons taught by the universe, and the less reason will there be for resigning ourselves to the belief that thus far and no farther may we go.

◆

Colonies for Epileptics.

THE letter from our Australian correspondent which appeared in THE LANCET of August 13th contained an account of a deputation organised by the National Council of Women which recently waited on the Minister of Lands to obtain, if possible, a grant of an area of land suitable for the establishment of a colony for epileptics. The deputation pointed out that in the community of Victoria there were from 1600 to 2000 persons suffering from one of the most distressing afflictions with which humanity is acquainted. Only one-fifth of the number of known epileptics could be provided for in existing institutions, and the deputation further pointed out that epileptic children were prevented from obtaining occupation in the ordinary way and that the development of the disease was favoured by the want of proper mental training. The Minister's reply was of the usual kind. It sounded stereotyped and temporizing, but it must be recognised that on the spur of the moment responsible officials can only respond to deputations in this way. Nothing is gained by the promise of reforms or innovations which the Government may not be able to carry out. The Minister of Lands said that his entire sympathy was with the deputation and that he would see what could be done, but the question of available land that was also suitable could not be settled offhand.

Epilepsy has from the earliest ages been regarded as peculiarly distressing and its pathology is in many directions still unknown to us. The suddenness of the attack, the racking convulsions, and the falling down gave the old observer the impression of an onslaught by some evil spirit, and hence the Greek term for the disease, ἐπίληψις. Hence, also, possibly the word used by our Anglo-Saxon ancestors "onfall," though it is not known for certain what "onfall" was. But it is almost certain to have been epilepsy, so well known to the people under its common title, the "falling sickness." Owing to the uncertainty of the time of the attacks and in many instances to their occurrence without any warning or "aura" the epileptic is rendered quite unfit for most ordinary occupations of life. Unless he can be constantly watched by someone he must be ever in peril and perhaps a source of peril to the community. He may injure himself by the mere violence of his fall, in crowded streets he may be run over, or, as of old, it may be that "ofttimes he falleth into the fire or into the water." He is a burden to himself and to his friends. An epileptic among the labouring classes is almost precluded from obtaining any employment whatever, while as for treatment, although the effects of the administration of one of the bromides are very marked and in many cases, up to a certain point at least, successful, yet, as Sir WILLIAM GOWERS has remarked, "bromide has its drawbacks. It is not surprising that it should often interfere with the normal function of the brain; the marvel is that it should so often arrest the abnormal and leave the normal almost or completely undisturbed." The difficulties which encompass the life of an epileptic have therefore led to the establishment of colonies in which those suffering from epilepsy can live under the care of those who can tend them during an attack and ward off the dangers. A peculiarly sad feature about this disease is that it can exist coincidently with the highest mental and moral qualities and, without going so far as some modern writers have done in this direction, it may safely be said that many men of genius have been epileptic. On a lower mental scale than this the epileptic during the interval between his attacks is quite capable of doing useful work, such as gardening or carpentering, and it is those forms of employment which are generally afforded in an epileptic colony. In this country such colonies have been established at Godalming, at Chalfont St. Peter, at Chelford in Cheshire, at Maghull near Liverpool, and one quite recently under the auspices of the London County Council at Ewell. In other countries the most notable one is Craig Colony in the State of New York, but this colony, like that at Chalfont St. Peter, only receives patients who are comparatively sane and free from obvious evidence of cerebral paralysis. The Ewell colony, on the other hand, was established with a view to the reception of the epileptic insane who were formerly under care in the metropolitan asylums. Such patients, although they may be insane, are yet, if free from dangerous delusions and criminal instincts, admirably fitted for farming and industrial colonies. They are capable of being educated, and if set to work in an institution where their special affliction may be cared for their labours may be remunerative to the extent of rendering the institution to a considerable extent self-supporting. On the other hand, if left to find their own living in the world at large they would most probably starve, for their labour, intermittent as it must be, has but a small market value.

We presume that the numerous epileptics referred to by the deputation of the National Council of Women of Victoria include many sane as well as insane, and, moreover, only women and girls are to be treated at first, while all patients are to pay something for maintenance, the sums varying from £2 to 7*s.* 6*d.* per week, so that the proposed Australian colony cannot be intended, for the very poor. But doubtless it is intended to provide for this class in the future. It is a good thing to make a beginning and we hope that the Minister of Lands will not only "see what can be done" but will find that he can do something to meet the desire of the deputation. Of old time lunatics and epileptics were supposed to be under the special protection of the deity, in later times they were taken to be possessed by devils, and even after this notion was exploded they were treated by whipping and imprisonment. It was not until the last decade of the nineteenth century that the epileptic was reckoned as a fit subject for the care of the State. By the establishment of colonies Christian charity and social economy for once go hand in hand, for in such colonies the life of the epileptic is to a great extent freed from a crushing burden, his labour is made profitable, and the State is relieved from the possibility of having to support and deal with him should he degenerate both physically and mentally and become added to the large army of the criminal and degraded.

◆

The Clinical Causes of Cancer of the Breast.

WE discussed in a leading article last week the two main theories with regard to the etiology of cancer, but there is one aspect of the problem which has hardly yet received the attention that it deserves. Environment and soil, so much talked of in connexion with all evolutionary processes, have not been closely observed in the matter of cancer. In considering the reasons for the appearance of a disease we should not be satisfied merely with finding the actual exciting cause but we should also endeavour to trace out the various conditions which permit the exciting causes to act. No living being, whether plant or animal, can survive unless the surrounding conditions—its environment—will permit it to carry on its vital processes. The soil is as necessary as the seed and when, as is often the case, the seed is very widely scattered the presence or absence of the plant in any area may depend entirely on the suitability of the soil for supporting it. The hyphomyces of ringworm will flourish on the scalp of nearly every child but in very few adults is it able to grow at all. *Yet it must be very common of occurrence.* The same position prevails with many other diseases. The germs on which they depend may be found everywhere, but it is only here and there that a body is found which is suitable for the growth of the germ. For the production of tuberculosis no one will now deny that the presence of the tubercle bacillus is essential. But the tubercle bacillus is almost omnipresent, at least in most large towns, so that the numbers of persons attacked by tuberculosis is incalculably smaller than those who are exposed to the bacillus. Most of us must day after day inhale the tubercle bacillus but no harmful results occur. The seed is planted but it cannot grow [illegible] or it. If the bacillus of [illegible] ng in any and every human [illegible] nigh universal.

Whatever, then, may be the true cause of cancer, whether it be a parasitic microbe or an intracellular "influence," we must all agree that something else is needed to produce malignant disease—at any rate, upon analogy, it is overwhelmingly probable that such is the case. The other necessary conditions are, from one point of view, just as truly causes of the disease as the primo cause for which many are now seeking with tireless energy. Several investigations into these "clinical causes" of cancer have been made from time to time. WALSHE in 1846 published a volume on the nature and treatment of cancer and investigated very thoroughly the predisposing causes. A recent exposition of this aspect of the subject has been written by Mr. O. H. LEAF who has issued a small volume enumerating the conditions under which malignant disease of the breast may occur, and has tabulated his investigations so that some useful statistical conclusions may be drawn. Thus, for instance, we find that in 35 per cent. of the cases there was a definite history of injury and from this the writer concludes that trauma is a common factor in the production of cancer of the breast. There are many conditions mentioned in this volume which are suggested as of etiological importance, but the four chief "clinical causes" are given as errors of lactation, a family history of consumption, injury and anxiety. On the whole the writer concludes that cancer of the breast is almost invariably due to a combination of causes. We are of opinion that such an inquiry as this is work in the right direction, and similar inquiries in respect to cancer in other regions of the body might be instituted with advantage. Mr. LEAF has carried out his work with much care and thoroughness, and we appreciate fully the volume he has produced.

But our commendation and our suggestion that more work in a similar direction should be done by Mr. LEAF or others must not leave the impression that we are ignorant of the risks of the inexpert use of statistics. Few medical men ever have any training in the use of statistics—this is not a subject required for examination and therefore very few of them study it—and yet as a body the members of the medical profession have more to do with statistics than most other professions. The result is that in many articles and in many books written by medical men we find statistics used in a manner which much vitiates the conclusions drawn. We find something of this in Mr. LEAF's book. We may quote an instance. "84 per cent. were married, 16 per cent. unmarried," says Mr. LEAF, and continues, "Cancer of the breast therefore appears more than five times as frequently in the married as in the unmarried." Of course, the conclusion, if its apparent meaning is to be taken, is absolutely unwarranted by the facts presented. From the statement that 84 per cent. were married and 16 per cent. were unmarried the only valid conclusion that can be drawn is that amongst the cases on which Mr. LEAF's statistics are based there were five times as many married as unmarried women. Before we can draw any conclusions as to the relative frequency of cancer of the breast in married and unmarried women we must know the relative frequency of married and unmarried women in the general population. Moreover the relative frequency should be known in the same district from which the patients came and from the same class of the population and between the same ages as the patients who were used for the statistics. It is obvious in every local prison and we echo her wish. In one point we think that she is unduly pessimistic and that is in her expression of opinion that the convict woman is irreclaimable. No one, we believe, is hopelessly irreclaimable, unless insane. Those of our readers who can call to mind Walt Whitman's magnificent poem, "The Singer in the Prison," will know what we mean, although the poet was writing of male prisoners. It is a psychical fact that a woman criminal is far more difficult to reclaim than a man, but nothing is more likely to make a bad character confirmed in bad habits than for reclaiming agencies to plead that nothing can be done for his or her improvement. The Association of Lady Visitors has already done magnificent work in persuading convicts who have expiated their offences to desire a better life and Miss Smith-Rossie may think of Whitman's words:—

> "A soul confined by bars and bands,
> Cries, Help! O help! and wrings her hands;
> Blinded her eyes, bleeding her breast,
> Nor pardon finds, nor balm of rest.
>
> Ceaseless she paces to and fro,
> O heartsick days, O nights of woe!
> Nor hand of friend, nor loving face,
> Nor favour comes, nor word of grace.
>
> It was not I that sinned the sin,
> The ruthless body dragged me in;
> Though long I strove courageously
> The body was too much for me.
>
> Dear prison'd soul, bear up a space,
> For soon or late the certain grace ......"

The way of the released convict is by no means easy but difficult and thankless as the task of helping such may seem the word "irreclaimable" should not be found in the vocabulary of the prison reformer.

THE TEMPLE OF ASKLEPIOS IN THE ISLAND OF COS.

DR. RICHARD CATON and various writers upon antiquarian subjects have acquainted the public of the valuable results achieved a few years ago in the excavation by the Greeks of the celebrated sanctuary of Æsculapius at Epidauros, and M. Cavvadias, the official explorer of that site, in many monographs, and, finally, in a magnificent volume, has presented a complete account of his work and published all the inscriptions and relics found. The great success at Epidauros naturally suggested similar investigations at the other famous seat of medical lore and worship of the ancient Hellenic race, the Asklepeion, or temple of Asklepios, in the island of Cos. Six years ago a German archæologist, Herr Herzog, visited Cos for the purpose, if possible, of ascertaining the situation of the shrine but did not succeed in detecting its position. He, however, made a valuable preliminary survey. In 1900 he again returned to Cos on a mission from the Prussian Academy and the German Archæological Institute. His chief attention this time was given to examining the stones out of which the citadel of Cos, built in the fifteenth century by the Knight Hospitallers, was constructed, for they consist chiefly of the remains of ancient edifices, statue bases, and monumental stelæ, many bearing Greek and Latin epigraphical texts. For Herr Herzog they furnished 20 new and 50 partly known inscriptions but neither these nor others he discovered elsewhere gave him the desired clue to the Asklepeion. In 1902 the indefatigable observer returned once more, accompanied by an architect and a naturalist, Herr Hecht and Herr Vosseler, and commenced excavations in a temple of Demeter at Isthmos and then at an edifice dedicated to Apollo at Halasarua. Still these were not the Asklepeion. The corpus of the inscriptions of Cos had been edited by a British student, Mr. Paton, and in his commentary upon them he had called particular attention to the remains of a magnificent temple near the present village of Kermete. The land had once belonged to the convent of St. John, at Patmos, and in ancient manuscripts relating to that convent the site was called τὸ ἄλσος. Now Mr. Paton noticed ἄλσος was the name of woods which were sacred to Asklepios and suggested to the German searchers to try this site efficiently. The practical Englishman proved more prescient than the erudite Germans, for preliminary explorations speedily proved that the Asklepeion of Cos had been discovered. The great temple stood upon the side of a hill, 100 metres above the blue Ægean Sea, upon a platform from which can be seen Samos to the north, Calymoros to the west, and the Asiatic coast from Mycale to Halicarnassus. The whole of the edifice above ground was of white marble. The foundation of a long base was found which probably supported a pair of statues of Asklepios and Hygeia. Two other temples and a grand altar have been found close to the grand temple. This altar is certainly the one upon which two of the characters in a recently recovered poem of Herondas admired the statues of Asklepios and Hygeia by the son of Praxiteles. The great temple was built in the second century B.C. but its inscriptions range to the third century A.D. Among these texts one refers to a request from Gortyna, in Crete, to send them a medical man. Cos despatched one Hermias who bestowed such care on many Gortynians wounded in a campaign that he merited the honour of a grateful inscription. The school of medicine at Cos was evidently a place from which physicians were obtained. In 1903 Herr Herzog returned to Cos and has made many more discoveries, among others a head of Asklepios and numerous inscriptions. When these are all carefully edited we shall have as complete a record of the great medical college of Hippocrates as we have of the rival school at Epidauros.

COPPER IN PRESERVED PEAS AND BEANS.

FINES of £2 with £2 2*s.* costs and £1 with 2*s.* costs were inflicted by Mr. Marsham at Bow-street Police-court this week upon a wholesale grocer for selling preserved peas which contained 3·402 grains of sulphate of copper per pound and beans which contained 4·067 grains per pound. Medical evidence was given by Mr. A. D. Cowburn, acting medical officer for Holborn, who explained the cumulative effect of repeated doses of sulphate of copper and pointed out that though it might be administered medicinally the maximum dose in such a case would be considerably less than that contained in a pound of peas or beans as sold by the defendant. When only a small amount of copper was used it entered into combination with the chlorophyll forming phyllocyanate of copper. There was no direct evidence that phyllocyanate of copper in minute quantities was injurious to health, although dogs fed on this substance became paralysed, which paralysis ultimately caused death. When copper was used in such large quantities, however, as those stated in the analyst's report the copper entered into combination with the pith or substance of the pea or bean, forming leguminate of copper. He had ascertained from the analyst that leguminate of copper was present in both the articles in respect of which proceedings had been taken. There was a difference of opinion as to whether leguminate of copper was or was not acted upon by the gastric and pancreatic juices. When people, as they frequently did, used butter in cooking peas preserved with copper, complex organic compounds, one of which was oleate of copper, were formed, in which case a much larger quantity of copper was absorbed into the body. That had been proved by experiments carried out for the purposes of the Departmental Committee on Food Preservatives. The defence raised a point of law on the form of the certificate, while otherwise it was to the effect that the defendant had for many years sold similar goods to those on account of which he was prosecuted. The tin of beans had

had on it a label intimating that it contained sulphate of copper, and the tin of peas had, it was stated, borne a similar inscription which had fallen off Questions were put to Mr. Cowburn in cross examination with a view of showing that sulphate of copper, being used medicinally, was therefore harmless, or even beneficial, in vegetables ! It is to be hoped that when this last point is raised, where chemical substances have been introduced into foods as colouring matter or as preservatives, magistrates will remember that when poisonous drugs are employed as medicines they are prescribed for particular purposes by qualified medical practitioners and that the prescriptions are then made up by competent and responsible druggists The addition of such drugs to foodstuffs in order to attract customers is upon a different footing, if only because there is no proof that trustworthy steps have been taken to secure the proper proportion of the dangerous substance, and no more, appearing in a given quantity of the article sold

CHANGES IN THE BLOOD IN MENTAL DISEASE.

A VALUABLE paper on the subject of the leucocytic changes in the blood in various forms of mental disease is contributed to the *Journal of Mental Science* for July by Dr. Lewis C Bruce, medical superintendent of the Perth District Asylum, and Dr A S M. Peebles, assistant physician A systematic examination was made of the blood of 150 patients admitted to the asylum during the past three years Each patient's blood was examined on several (three or more) occasions, often for weeks or months at a time, during the varying course of illness As regards technique Cole's system of counting "fields" was employed in the blood examinations to determine the frequency of the leucocytes The Thoma Zeiss hæmocytometer was employed and no less than 30 fields, and frequently more, were counted at each enumeration when accuracy was desired The specimens were coloured with Louis Jenner's stain In the differential countings the following five varieties of leucocytes were recognised—viz , polymorphonuclear leucocytes, small and large lymphocytes, eosinophile leucocytes, and mast cells For purposes of comparison numerous control counts were also made from the blood of members of the asylum staff In these control cases the leucocytes were found to be from 6000 to 9000 per cubic millimetre of blood in young healthy males and from 6000 to 13,000 in females The average percentages of the different kinds of cells were as follows polymorphonuclear cells 70 per cent , small lymphocytes 20 per cent , large lymphocytes 8 per cent , and eosinophile cells 1 5 per cent in the males, the corresponding figures for females being 60, 30, 7 5, and 2 per cent Mast cells says Dr Bruce, occasionally occurred and a percentage of from ½ to 1 was met with in the control specimens of blood The following were the general results obtained in this investigation, the details in each of the individual cases of disease conforming in general to the average results obtained for each class In cases of pure acute melancholia leucocytosis was never observed to be present The leucocytes varied from 7000 to 13,000 per cubic millimetre, the polymorphonuclear cells from 55 to 70 per cent , the small lymphocytes from 30 to 40 per cent., and the large lymphocytes from 5 to 10 per cent The eosinophile cells never exceeded 1 per cent and in a few cases an occasional mast cell was seen A useful practical inference is drawn here In examining an early case of melancholia which has not yet fully developed, says Dr Bruce, "the prognosis should be guarded if hyperleucocytosis is present and especially if the polymorphonuclear percentage is above 70 On the other hand, if the leucocytosis is below 10,000 the prognosis is good for the melancholia " In cases of excited melancholia examination showed a high leucocytosis early in the disease, and coinciding with this the percentage of polymorphonuclear cells was frequently above 70 Later in the disease during relapses and recurrences a high leucocytosis (20,000 to 30,000 per cubic millimetre) and a high polynuclear cell percentage (80 per cent) frequently prevailed Before the onset of the relapse both percentages were low, the rising numbers of leucocytes and polymorphonuclear cells being associated with the exacerbation of the illness Cases of mental excitement which on further examination turned out to be "*folie circulaire*" often might, adds Dr Bruce, be mistaken for simple acute mania All such cases when examined showed depression or excitement of the simple melancholic or maniacal type During the stage of depression all these cases exhibited a high leucocytosis with a polymorphonuclear percentage of from 60 to 70 When apparent recovery followed the leucocytosis still remained high, and when excitement set in the leucocytosis gradually increased, reaching its height at the acme of the mental disturbance and then gradually falling to a lower level The depression and excitement of cases of "*folie circulaire*" are quite different from ordinary attacks of mania and melancholia The leucocytosis of acute continuous mania and of recurrent mania in adolescents exactly resembles that of excited melancholia and a notable feature in all three conditions was its persistency. Leucocytosis remained for months, and even in some cases for years, after the patient's recovery and discharge from the asylum In cases of recurrent mania (not including alcoholism) the leucocytosis rose high during the attack and fell slightly afterwards but rarely reached the normal The polymorphonuclear percentages followed the curve of leucocytosis Between the excitement periods of recurrent mania the large lymphocytes and hyaline cells of the blood were much increased, often reaching 20 per cent In alcoholic acute mania the blood changes were identical with those of non alcoholic acute continuous mania, which suggested to the authors of the investigation that "alcohol was an exciting cause, breaking down the resistive power of a patient predisposed by heredity to the infection which occurred in melancholia " Chronic alcoholic cases (delusional type) never exhibited any leucocytosis. All cases of paranoia and of delusional insanity occurring in later life were entirely free from hyperleucocytosis In classical cases of general paralysis there were hyperleucocytosis and a high polynuclear percentage at the onset, with marked remission of symptoms if the leucocytosis had been very *high during* the attack During the second stage of general paralysis the leucocytosis followed the course of the disease, febrile attacks being heralded by rise of the percentage of both polymorphonuclear cells and small lymphocytes Transient [illegible] during the seizures and in the intervals, the most marked increase of cells following a series of fits (status epilepticus) No cells exhibiting any evidences of phagocytosis were ever found in any of the cases of insanity examined

THE MEMORIAL TO SIR THOMAS BROWNE

IN THE LANCET of May 27th, 1899, we published a letter from Sir Peter Eade, the chairman of a committee appointed to organise the raising of a statue to be erected in Norwich to Sir Thomas Browne As will be seen by a letter which appears in another column from Mr F R Eaton, the honorary secretary of the fund, the preliminary arrangements for the statue are now complete and Mr Henry Pegram has been commissioned to carry out the work Sir Thomas Browne was one of the most famous citizens of Norwich, which he made his home, although he was not, strictly speaking, a native [illegible]astern.

capital. He was born in London and received his medical education in Winchester, but his name and fame are so intimately connected with Norwich that it is but fitting that his memorial should be erected there. No words from us are necessary in praise of a man whose writings are known throughout the English-speaking world, and the "Religio Medici" and still more his treatise on Urn Burial will remain as a possession for ever to all who can admire writing of a style which is at once philosophical, musical, and endued with that spirit of quietism which throughout the troublous times of the seventeenth century distinguished such men as Browne, Henry Vaughan, and George Herbert. The site suggested for the statue is in the Haymarket, near the house in which Browne resided for many years and the church of S. Peter Mancroft in which he was buried.

CHRONIC INTERSTITIAL NEPHRITIS IN THE YOUNG.

Chronic interstitial nephritis is very rare in the young. Ashby and Wright, in their text-book on "Diseases of Children," state that five cases have come under their observation—three cases in girls (aged respectively 11, ten, and seven years) and two cases in boys (aged respectively five and two years). In all the cases the diagnosis was verified by a necropsy. In the *American Journal of the Medical Sciences* for June Professor J. L. Hirsh has reported two cases, both associated with changes in the blood-vessels though of an entirely different nature. In the first case a boy, aged 15 years, was taken to hospital for uncontrollable bleeding from the gums following the extraction of a tooth on the previous day. He had been a robust child and had had measles at the age of six and varicella at the age of eight years. About a year before admission he began to complain of feeling tired after slight exertion, his appetite began to fail, and his sleep became restless. He got up at night to micturate. Of late he had had headache at irregular intervals. He had never suffered from hæmorrhage previously and there were no bleeders in his family. On admission he was pale, the mucous membranes were almost colourless, and he complained of dyspnœa. There was visible pulsation of the carotids. A slight râle was occasionally heard at the bases of the lungs. The apex beat was prominent and in the fifth space just outside the nipple line. The area of cardiac dulness was increased both towards the right and the left. There was a soft apical systolic murmur and the second aortic sound was accentuated. The radial pulse was full, of moderate tension, and, though compressible, was obliterated with some difficulty. The liver extended a finger's breadth below the costal margin. The urine was increased in quantity, pale, and of specific gravity 1012. It contained a little albumin and a few hyaline casts and an occasional granular cast. At times albumin was absent. Continuous pressure stopped the hæmorrhage in a few hours. After resting in bed for a few days his condition seemed to improve but after he had been up for a week œdema of the ankles was observed. The dyspnœa increased and he died five weeks after admission. At the necropsy about 200 cubic centimetres of serous fluid were found in each pleural cavity. The lungs were congested and œdematous. The heart was enlarged, principally from hypertrophy of the left ventricle, which was two centimetres in thickness. The left kidney weighed only 68 grammes and the right 80 grammes. Both were granular. The aorta was atheromatous and showed calcareous plates and spots of fatty degeneration. Microscopic examination of the kidneys revealed great increase of connective tissue, destruction of glomeruli, and degeneration of the tubes. In the second case a girl, aged 18 years, was admitted to hospital on July 12th, 1903, complaining of frequency of, and loss of control over, micturition. The symptoms began two years before. She was anæmic and her development corresponded to that of a girl aged 14 years. Moist râles were heard over both lungs. The cardiac dulness was increased and the apex beat was one centimetre outside the nipple line. The aortic second sound was accentuated. The urine was increased in quantity, pale, and of specific gravity 1010. It contained a few hyaline casts and a little albumin. The lower limbs were œdematous. On July 25th she began to complain of headache and became dull and two days later comatose. She died on the 28th. The necropsy showed an enlarged heart. The kidneys were very small and granular. The aorta was abnormally small and admitted the little finger with difficulty. A relation between congenital narrowness of the aorta and primary atrophy of kidney has been described by Lanceraux and others. The etiology of granular kidney in the young is obscure. It has been described as congenital and congenital syphilis has been supposed to play an important rôle in its production. Heredity seems to be a factor, as in the remarkable case cited by Dr. Howship Dickinson in which Bright's disease appeared in four generations.

THE ALCOHOL HABIT AND THE AUTOMATIC MACHINE.

Not long ago considerable publicity was given to the fact that certain sweets contained a decided quantity of alcohol, but this is not the only surreptitious way of imbibing the spirit, as would appear from a method of which a correspondent informs us he has been recently an eye-witness. It is well known that strong spirit is an indispensable solvent for essential oils in the preparation of perfumes. Their alcoholic strength, of course, varies, but we should be well within the mark we think if we suggest that, generally speaking, perfumes are stronger than brandy. Such is the depraved state of human nature even in its early stages that the automatic penny-in-the-slot machine has been found by small boys to be a source of free "nips." There are automatic machines designed for supplying a sprinkling of scent for the handkerchief for the sum of one penny. A handkerchief is placed upon a metal cup above which is a delivery tube or spout. On putting a penny in the slot a small quantity of perfume is discharged from the spout and scattered on the handkerchief. Certain ingenious little urchins, it appears, have not been long in discovering that what costs the customer the sum of one penny for the luxury of having a handkerchief scented may be obtained free by applying a partial vacuum at the end of the spout, otherwise by the eminently simple means of sucking. The fact that sucking anything, nice or nasty, wholesome or insanitary, is a perfectly natural habit in the young would discount any claim on the part of these wicked boys to a particularly original design. The spout was clearly meant to deliver something and it was but an instinctive thought to see if something could be got out of it. The experiment was a success and we need hardly dwell upon the evil possibilities of the urchins' discovery. We trust, and do not doubt, that the companies who own these machines will take preventive steps.

The medical officer of health of the Cape Colony reports that the state of the colony for the week ending July 23rd as regards plague was as follows. At Port Elizabeth three cases of plague were discovered during the week; 202 rats and 171 mice were bacteriologically examined during the week, and of these 12 rats and nine mice proved to be infected with plague. At East London the carcass of a rat discovered on July 21st was considered on microscopical examination to be probably plague-infected and inoculation experiments are being carried out to test this view. In the Harbour Board area and the Cape Town municipal area 553 rodents were examined but none was found to be plague-infected.

THE King of Greece has conferred the Gold Cross of the Royal Order of the Saviour upon Sir William Bennett, K.C.V.O., F.R.C.S.

THE REPORT OF THE PRIVY COUNCIL UPON PHYSICAL DETERIORATION.

(Continued from p. 502.)

HAVING discussed in the earlier portion of its report the value of the evidence presented by the War Office, and having satisfied itself of the failure of the data officially relied on to prove general physical deterioration, the committee comments with justice, and evidently with surprise, on the absence of any criteria, statistical or otherwise, by which a comparative estimate of the health and physique of the community may be arrived at. Accordingly, in compliance with the terms of its reference, the committee addressed itself at an early date to the task of supplying this pressing want for future use. It has accordingly devised a plan by means of which information as to certain broad facts regarding measurement, health, and physique may in course of time become available for State purposes. In order that this plan should bear the stamp of scientific authority the committee invited the assistance and counsel of the English Royal Colleges of Physicians and Surgeons, as well as that of the leading anatomists, anthropologists, and other scientific men whose advice was likely to prove useful. The labours of the committee in this direction have resulted in a scheme which is fully set forth in the report and to this we shall recur later.

In commenting on the evidence of many competent witnesses the committee refers to the practically unanimous testimony received as to the improving conditions under which the denizens of our large towns are now called upon to exist. Rookeries are being dispersed, inclosed yards opened out, cellar dwellings and back-to-back houses are disappearing, and, speaking generally, daylight and fresh air are being admitted into slum property from which the avarice of the land-grabber and the jerrybuilder had excluded both these essentials of healthy life. Concurrently with an increase of wages a fall in the price of most of the necessaries of life has taken place, more than counterbalancing the rise of rent which in itself is largely due to the higher wages now paid in the building trades. In this connexion the valuable evidence of Mr. C. S. Loch, Secretary of the Charity Organisation Society, is especially referred to. He furnished the committee with reasons for believing that improved resources have been accompanied by an upward movement in social ability and competence, with the result that a certain amount of advantageous expenditure has gone in better dwelling-places and in the purchase of better and more plentiful food. From other witnesses, too, the committee learns that in various directions the conditions of life among the labouring classes have been improved. For example, a better and more abundant water supply has been in many cases secured, the housing of the working classes has been the subject of legislative concern, pauperism, especially among the young, has diminished, better and more complete hospital accommodation has been provided for the sick poor, the conditions of labour touching young persons and women in factories and workshops have been greatly ameliorated, and all the "children of the State" in workhouses, schools, reformatories, and industrial institutions are started in life under more fortunate auspices than formerly. In short, the mass of evidence which the committee has received is practically conclusive as to the non-existence of any general or progressive deterioration either in the physique or in the health of the British nation. On this point we may quote from the report the deliberate judgment of the committee. "*It may be as well to state at once that the impressions gathered from the great majority of the witnesses examined do not support the belief that there is any general progressive physical deterioration.*"

The first volume of the evidence on which this important judgment is founded was published last week, and from such a perusal of it as has been practicable in a few days we believe that our readers will agree with the verdict which, after long and painstaking inquiry, the committee has pronounced. There is, however, on the other hand, a dark side to this picture, and this the committee has not failed to recognise and to deplore. Without question there still exists in London as well as in other large British towns a considerable aggregate of slum population, ill-nourished, disheartened, poor, ignorant, badly housed, miserably clad, and, indeed, hardly amenable to social improvement. In the absence of trustworthy data the committee expresses no opinion as to their number, but it speaks of these slum dwellers as the "degenerates." These are the luckless denizens of our large towns and the prominent notice now directed to the physical condition and environment of the lower classes is responsible for the notoriety they now enjoy. Physical infirmity is practically limited to the poorest and lowest strata of the population, whose children are improperly fed and inadequately lodged, and in which the parents of both sexes are idle, improvident, and intemperate. With reference to these wretched persons the committee observes that in large classes of the community there has not been developed a desire for improvement commensurate with the opportunities offered to them. Laziness, want of thrift, ignorance of household management, and particularly of the choice and preparation of food, on the one hand, and, on the other, filthiness, indifference to parental obligations, and drunkenness largely affect adults of both sexes and press with terrible severity upon their offspring. "The people perish for lack of knowledge." Local authorities, moreover, especially in country districts, are often reluctant to exercise their powers, and in these circumstances sanitary progress, lacking the stimulus of a healthy public conscience, is tardy and uncertain.

Foremost among the many causes in operation that are calculated to arrest and depress development is the massing of the population in great towns—the "urbanisation of the people." The recent census returns tell us that the urban portion of the population of England and Wales now equals nearly four-fifths of the whole, whereas 50 years ago it was little more than half, and further, that for every person who in the year 1851 lived in a town about three persons are town dwellers at the present time. It must, however, be borne in mind that the meaning of the term "urban" is frequently misunderstood; the term does not mean more than that the area to which it applies has, for purposes of local government, an urban organisation. As a matter of fact, a large portion of the dwellers in so called urban districts are now living under conditions as healthful as any that obtain in rural districts. Owing to the greater completeness of sanitary legislation and the higher conception of duty that governs their administration these urban areas enjoy advantages that are denied to the rural, and it is a fact that towns have at the present day a death-rate which compares favourably with that of country districts half a century ago.

Prominent among the results of urbanisation stands overcrowding, with its attendant evils of uncleanliness, foul air, and bad sanitation. Overcrowding, says Mr. Charles Booth, is the great cause of degeneracy. Drink is fostered by bad houses. Crowded homes send men to the public-house and are the main cause of drink and vice. Unfortunately, the permanent difficulty in the way of improvement lies in the character of the people themselves—their feebleness and indifference, their reluctance to move, and their incapability of moving. These are the real obstacles that beset even well-disposed local authorities in their endeavours to ameliorate the conditions of life in our great towns. The evils of overcrowding are of course most obvious in [illegible] he overcrowding t[illegible] e lowest type, stee[illegible] cynically indifferent [illegible] by their filthy habits and to the moral pollution of the young brought up in such an atmosphere. In Glasgow the general death-rate in single-roomed tenements is just twice that of the whole city, whilst the mortality from pulmonary tuberculosis is more than three times [illegible] houses. In Finsbury, [illegible] cent census, no less than [illegible] tenements, the death-rate at all ages was 39 per 1000 living, notwithstanding that in the same borough the rate among occupants of four-, or more, roomed tenements was less than 6 per 1000. In seven groups of districts in the administrative county of London the mortality among infants closely follows the degree of overcrowding. In other words, in districts where the proportion of single-roomed tenements does not exceed 10 per cent. of the whole the infantile death-rate is 146 per 1000, but as the proportion of the people living in overcrowded tenements increases so does also the infantile death-rate, ranging from 180 per 1000 in some districts through 196 and 210 per 1000 and culminating in the most crowded districts in a rate of 223. We thus see that in the districts last mentioned out of every four children born one dies before reaching its first birthday, and with all due respect for the War Office authorities we would remark that this fact is of far greater national importance than is the other fact that three out of five slum-dwellers recruited for the army are eventually found unfit to remain with the colours.

In so far as the evils of overcrowding depend upon structural defects of slum property the committee holds that they are gradually removeable by the firm application of existing statutory powers. The fact, however, is established by the evidence of many witnesses that much of the insanitary property is in the hands of persons who, as members of the sanitary authority, are called upon to put the law in operation. Recognising the paralysing effect of this circumstance the committee approves of the suggestions of Colonel Lamb of the Salvation Army to the effect that in all cases involving the amelioration of slum property justice should be administered not as at present but by a stipendiary magistrate. With regard to the incorrigibles, the habitual vagrants and so-called "won't works," the committee thinks that the system of "labour colonies" as now carried out by the Salvation Army at Hadleigh might be worthy of a fair trial. The committee paid a visit to this colony and was much impressed with the order and excellent management which pervaded every branch of its administration and by the opportunity the system there in operation on a large scale appears to offer for the reclamation of the waste elements of society. Having regard to the desirability of preserving the young from contaminating influences it might be possible to apply similar treatment to the children of all parents who have proved unfit to discharge their obligations to those whom they bring into the world. With a view to the enforcement of parental responsibility the object would be to make the parent the debtor to society on account of his child, with the further liability in default of payment for suitable maintenance of being placed in a labour colony under State supervision until the debt is discharged. It is not believed that such extreme measures would be necessary in a large number of cases; the fact that a few defaulters had been so treated and that the State had the necessary power would exercise a salutary effect and might be expected to prove to the young a charter of immunity from the worst of the evils by which they are at present oppressed. According to the evidence, the Staffordshire Potteries appear to suffer exceptionally from the neglect of local authorities to deal with glaring offences against sanitary law. Thus one witness said, "I should think that the local authorities in the Potteries were as inefficient as you could find anywhere." Most of the bad houses are owned by members of the local bodies and the sanitary inspectors are too much in awe of their employers to carry out their duty. For this state of affairs the remedy is obvious and is one which the committee approves. It consists in applying to the chief administrative officer of each local authority the principle carried out in London to the benefit of all concerned—namely, that of granting to the medical officer of health secure tenure of office provided that he satisfies the Local Government Board as to the manner in which his duties are performed and that he devotes his whole time to sanitary work.

Among other alleged causes of physical deterioration associated with aggregation of the people in towns is the withdrawal from the rural districts of the best and choicest of the population, leaving weaker and inferior types to continue the stock. This evil is sometimes aggravated by the drifting into the country of the debilitated town population which is crowded out by the inrush of more vigorous elements. Evidence given before the Scotch Royal Commission on Training suggests that the physique of the population of the home counties had suffered by the outflow of debilitated types from the metropolitan area. Moreover, Mr. Tweedy, the President of the Royal College of Surgeons of England, in the course of his remarks on the migration of the stronger types into the towns, expressed the opinion that a reverse process was going on; that there is a current of the better and more adventurous people into the towns and also a similar reverse current of the feebler and less fit who are driven back again to the land, the rural districts thus becoming at once the recruiting ground and the asylum of the towns. This aspect of the question has especial interest for Ireland. The witnesses from that country were emphatic in ascribing to emigration fatal effects upon the physique of the people by withdrawal of the strongest and best types, thus leaving it to the weakest types to reproduce their kind and carry on the race. The sound and the healthy—the young men and young women—from the rural districts emigrate to America and other lands in great numbers and, as a rule, it is only the more enterprising and more active that go. By the combined operation of these causes the flower of the rural population is depleted and an undue proportion of weaklings constitutes the stock from which the population of Ireland is recruited. The committee proceeds to consider the alleged tendency of the superior stocks in all classes of the people towards a *diminished rate of reproduction as one of the possible causes* of physical deterioration. So far as this allegation is based upon a diminishing birth-rate—a fact general throughout Western Europe—there appear, in the committee's judgment, to be certain compensatory considerations. Among the factors in the reduced birth-rate in England are: (1) the raising of the ages at which marriages are contracted; and (2) a diminution in the number of illegitimate births. Both these circumstances are believed by the committee to tend to the improvement rather than to the deterioration of the race.

(To be concluded.)

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following are the awards recommended by the committee of distribution for the year 1904:—

GENERAL HOSPITALS.

Charing Cross Hospital, £987 1s. 8d; French Hospital, £325 16s. 8d.; German Hospital, £565 8s. 4d.; Great Northern Central Hospital, £1030 4s. 2d.; Guy's Hospital, £2041 5s.; Hampstead General Hospital, £204 2s. 6d.; Italian Hospital, £182 1s. 8d.; King's College Hospital, £1458 11s. 8d.; London Hospital, £4992 18s. 4d.; London Homœopathic Hospital, £533 15s. 10d.; Phillip's Memorial Homœopathic Hospital, £23 [illegible] Hospital, £798 11s. 8d.; Metropolitan Hos[illegible]spital, £282 14s. 2d.; Miller Hospital and [illegible] 6 16s. 8d.; North-West London Hospital, £505 0s. 10d.; Poplar Hospital, £661 5s. 0d.; Queen's Jubilee Hospital, £153 6s. 8d.; Royal Free Hospital, £1341 13s. 4d.; St. George's Hospital, £1620 3s. 4d.; SS. John and Elizabeth Hospital, £327 15s.; St. Mary's Hospital, £2395 16s. 8d.; Seamen's Hospital Society, £1386 14s. 2d.; Middlesex Hospital and Convalescent Home, £2501 5s.; Tottenham Hospital, £445 12s. 6d.; University College Hospital, £1760 9s. 2d.; Walthamstow, &c., *Hospital*, £105 8s. 4d.; West Ham Hospital, £531 17s. 6d.; West London Hospital, £1015 16s. 8d.; Westminster Hospital, £1533 6s. 8d.; and St. John's Hospital, Lewisham, £191 13s. 4d.

CHEST HOSPITALS.

City of London Hospital for Diseases of the Chest, Victoria Park, £929 11s. 8d.; *Hospital for Consumption, Brompton*, £1820 16s. 8d.; Mount Vernon Consumption Hospital, Hampstead, £766 13s. 4d.; Royal Hospital for Diseases of the Chest, City-road, £431 5s.; and Royal National Hospital for Consumption, Ventnor, £335 8s. 4d.

CHILDREN'S HOSPITALS.

Alexandra Hospital for Hip Disease, W.C., £297 1s. 8d.; Banstead Surgical Home, £23 19s. 2d.; Barnet Home Hospital, £43 2s. 6d.; Belgrave Hospital for Children, S.W., £76 13s. 4d.; Cheyne Hospital for Incurable Children, S.W., £138 19s. 2d.; East London Hospital for Children, Shadwell, E., £805; Evelina Hospital for Sick Children, Southwark, S.E., £95 16s. 8d.; Home for Incurable Children, Maida-vale, W., £71 17s. 6d.; Home for Sick Children, Sydenham, S.E., £129 7s. 6d.; Hospital for Sick Children, Great Ormond-street, W.C., £1102 1s. 8d.; Kensington, for Children, and Dispensary, £81 9s. 2d.; North-Eastern Hospital for Children, Hackney-road, N.E., £431 5s.; Paddington-green Hospital for Children, W., £306 13s. 4d.; St. Mary's Hospital, Plaistow, E., £258 15s.; St. Monica's Hospital, Brondesbury, N.W., £67 1s. 8d.; Victoria Hospital for Children, King's-road, Chelsea, S.W., £527 1s. 8d.; Victoria Home, Margate, £40 5s.; and Hospital for Hip Disease, Sevenoaks, £43 2s. 6d.

LYING-IN HOSPITALS.

British Lying-in Hospital, Endell-street, W.C., £43 2s. 6d.; *City of London Lying-in Hospital*, City-road, E.C., £100; *Clapham Maternity Hospital*, £19 5s. 4d.; *East End Mothers'* Home, £67 1s. 8d.; General Lying-in Hospital, Lambeth, S.E., £59 8s. 4d.; and Queen Charlotte's Lying-in Hospital, Marylebone-road, W., £450 8s. 4d.

HOSPITALS FOR WOMEN.

[illegible] n, S.W., £273 2s. 6d.; Hospital for [illegible] 7, 15s.; Grosvenor Hospital for Women [illegible] S.W., £143 15s.; New Hospital for [illegible] £287 10s.; Royal Waterloo Hospital for Children and Women, Lambeth, S.E., £191 13s. 4d.; and Samaritan Free Hospital, Marylebone-road, W., £335 8s. 4d.

OTHER SPECIAL HOSPITALS.

[illegible] Frith street, W., £22 0s. 10d.; Royal Dental Hospital of London, W C., £213 14s. 2d.; and National Dental Hospital, 149, Great Portland-street, W., £30 13s. 4d.

CONVALESCENT HOSPITALS.

[illegible] oor Children, £20 2s 6d., St. Michael's Convale [illegible] 33 10s. 10d.; Seaside Convalescent Hospital, Seaford, £95 16s. 8d.; and Richmond House, Worthing, £19 3s. 4d.

COTTAGE HOSPITALS.

[illegible] am Cottage Hospital, [illegible] Hospital, £91 0s. 10d., [illegible] y Heath Cottage Hos- [illegible] Hospital, £59 8s. 4d.; [illegible] ospital, £57 10s.; Cold- [illegible] Hospital, £47 18s. 4d.; [illegible] n and Ewell Cottage [illegible] £43 2s 6d., Kingston [illegible] ge Hospital, Dartford, [illegible] 3s. 4d.; Reigate and [illegible] up Cottage Hospital, [illegible] Hospital, £38 6s. 8d.; [illegible] mbledon Cottage Hos- [illegible] Hospital, £38 6s. 8d.; [illegible] £47 13s. 4d.

INSTITUTIONS.

[illegible] House, Pembridge square, W., £95 16s. 8d.

DISPENSARIES.

[illegible] £55 11s. 8d.; Forest-hill Provi [illegible] Provident Dispensary, £31 12 [illegible] £15 6s. 8d.; Hampstead Provident Dispensary, £52 14s. 2d.; Holloway [illegible] chapel Provident Dispensary, £35 9s. 2d.; and Woolwich Provident Dispensary, £22 0s 10d

MEDICINE AND THE LAW.

Niall v. Tredgold.

AT both the summer and winter meetings of the General Medical Council of last year the case of Dr. William George Niall was heard *in camerâ*, with the result, it may be remembered, that the Council found the charges brought against him to be without foundation. This completed the case as far as the jurisdiction of the Medical Council was concerned, but circumstances have since arisen calling public attention to the matter. The case of Niall *v.* Tredgold, heard before Mr. Justice Joyce in chambers in the Chancery Division a few days back, was the direct outcome of the proceedings before the General Medical Council and possessed certain features of interest to medical men generally. The story told very briefly is as follows. Dr. Niall took Mr. A. F. Tredgold into partnership in 1901, but early in the year 1903 Mr. Tredgold informed him that unless he agreed to a dissolution of the partnership, a return of £230 of the purchase money, and undertook not to reside or have a surgery or place of call within a mile of his former residence a complaint of professional misconduct would be made against him to the General Medical Council. Dr. Niall denied that there were any grounds for such imputations, demanded names and full particulars, and protested against the indignity of having his name dragged before the Council. He also, not unshrewdly, suggested that a deed of dissolution should be drawn up on the terms verbally demanded from him. This was actually done and Dr. Niall, in possession of the draft deed, declined to complete the negotiations for a dissolution until "all imputations were withdrawn or made in such a manner that they could be threshed out." In reply to this Mr. Tredgold appears to have given seven days' notice of dissolution of the partnership and further to have replied that if the matter was settled quietly no names need be mentioned, but unless he had a reply agreeing to the terms by eight o'clock that evening he would proceed to the Council. The case came before the Council, as we have said, in May, 1903, when it was notified to Dr. Niall that the Medical Defence Union would conduct the prosecution. The case was first heard *in camerâ* in May and adjourned on the application of counsel for the defence until November for the production of rebutting evidence, when by the unanimous finding of the Council it was decided that the allegations against Dr. [illegible] false.

[illegible] don and Counties Medical Protection Society took [illegible] Dr. Niall's interests. On June 7th, 1904, a writ [illegible] d by the Society's solicitor on Mr. Tredgold as [illegible], Dr. Niall's claim being for: (*a*) A declaration [illegible] notice of Feb. 9th, 1903, purporting to terminate the partnership then existing between plaintiff and defendant by virtue of articles of partnership dated Sept. 25th, 1901, is not effective or binding on the plaintiff and that the said partnership now exists; (*b*) dissolution of said partnership; (*c*) all necessary and proper accounts; and (*d*) costs. Mr. Justice Joyce adjudged that the partnership ought to be dissolved as from the date of this judgment, June 30th, 1904—i.e., he gave Dr. Niall what he asked for.

This is a case of considerable interest. Firstly, it illustrates the inconvenience of the existence of rival medical defence associations. If the secretary of the Medical Defence Union had known the answers forthcoming to the charges brought against Dr. Niall, as well as those charges, he could have advised Mr. Tredgold not to adopt an extreme and, as events have shown, misdirected course. If Mr. Tredgold had placed his interests in the hands of the London and Counties Medical Protection Association that society could have told him the error that he was making. Secondly, it shows the weakness of the General Medical Council as a quasi-legal tribunal. The *whole matter ought to have* been *dealt* with privately by arbitration. The hearing by the Council *in camerâ* of charges of disreputable conduct against a practitioner is a gravely inconvenient method of procedure, if only because of the fact that the proceedings instituted cannot be kept private. And when the hearing has to be protracted throughout a year the position of the accused man becomes an intolerable one. If arbitration cannot be arranged it is better that prompt and open legal proceedings be taken. The action of the General Medical Council will follow automatically upon the verdict.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

County Borough of Halifax.—Dr. J. T. Neech suggests when dealing with the subject of the spread of small-pox by tramps that power should be obtained to arrest the movements of these persons for 14 days or so. He thinks that this power should be bestowed upon the Local Government Board, which central authority should be enabled to declare a given area an "infected area" much in the same way as is now the case with the Board of Agriculture under the Contagious Diseases (Animals) Act. In the event of the Local Government Board declaring any given area to be an "infected area" all common lodging-houses and tramp wards would be placed in quarantine. How much simpler it would be to have compulsory revaccination as is the case in Germany. In discussing scarlet fever Dr. Neech refers to a little outbreak of seven cases of that disease in which each patient obtained milk from a certain farm. No trace of scarlet fever could be discovered at the farm but on examining the cows it was found that in the case of one the udder was diseased and that serous fluid and pus could be expressed therefrom. The secretion was examined but nothing resembling the streptococcus of scarlet fever could be isolated. There seem also to have been several cases of sore-throat and enlarged glands in connexion with this milk-supply. The facts available are not, however, sufficiently precise to enable a causal connexion between the milk and the scarlet fever and sore-throat prevalence to be made out. The large number of deaths from measles which occur in children aged from one to five years has led Dr. Neech to suggest that children should not be allowed to attend school before five years of age. He points out that the Education Acts do not require such attendance and that it would not be a great advance on this position to refuse such children admission altogether. There are many persons who will agree with this proposal.

City of Coventry.—Dr. E. H. Snell points out in his annual report that if the decline in the death-rate from pulmonary tuberculosis which has been going on for the last 60 years continues it may be anticipated that the disease will have become extinct before the middle of the present century. Although this may be perhaps a somewhat Utopian idea Dr. Snell's words on the subject of tuberculosis are well worth quoting as an illustration of the views of some of our more thoughtful medical officers of health. He says: "There is no doubt that the neglect of the first principles of hygiene, embodied in the words light, ventilation, and cleanliness, and all which they connote, have more influence over the occurrence of this disease that has hitherto been imagined. The application of these to its cure, as in the open-air treatment, is of infinitely less consequence than their application to the prevention of the disease. When all houses are properly lighted and properly ventilated by windows and doors that are opened the chances of the propagation of tuberculosis will indeed be small." It is important, Dr. Snell adds, to have regard to these general principles and not to become engrossed too fully in "details such as disinfection, the prevention of spitting, the consumption of tuberculous meat and tuberculous milk, and the isolation of the phthisical, which, however important they may be, can never by themselves be expected to eradicate the disease."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9277 births and 6482 deaths were registered during the week ending August 13th. The annual rate of mortality in these towns, which had been 14·1, 16·4, and 19·8 per 1000 in the three preceding weeks, further rose last week to 22·1 per 1000. In London the death-rate was 21·4 per 1000, while it averaged 22·4 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 6·8 in South Shields, 9·0 in Hornsey, 10·2 in Hastings and in King's Norton, 10·4 in Devonport, 10·5 in West Hartlepool, 10·7 in Blackburn and in Halifax, and 11·3 in Coventry; while the highest rates were 31·2 in Birmingham, 32·4 in Aston Manor, 33·0 in East Ham, 34·6 in York, 35·5 in Bootle, 35·7 in Wigan, 36·7 in Leyton, and 37·7 in Liverpool. The 6482 deaths in these towns last week included 2710 which were referred to the principal infectious diseases, against 793, 1255, and 2059 in the three preceding weeks; of these 2710 deaths, 2423 resulted from diarrhœa, 122 from measles, 74 from whooping-cough, 47 from diphtheria, 28 from scarlet fever, 13 from "fever" (principally enteric), and three from small-pox. No death from any of these diseases was recorded last week in Hastings, Bournemouth, or South Shields; among the other towns they caused the lowest death-rates in Devonport, King's Norton, Blackburn, Stockton-on-Tees, West Hartlepool, and Tynemouth; and the highest rates in West Ham, East Ham, Leyton, Walthamstow, Aston Manor, Liverpool, Bootle, York, and Hull. The greatest proportional mortality from measles occurred in Brighton, Stockport, Bootle, Salford, and Hull; from whooping cough in Burton-on-Trent, Bootle, Huddersfield, and Rhondda; and from diarrhœa in West Ham, East Ham, Leyton, Walthamstow, Birmingham, Aston Manor, Liverpool, Bootle, Burnley, York, and Hull. One fatal case of small-pox was registered in London, one in Coventry, and one in Stockport, but none in any other of the 76 large towns. The number of small-pox patients in the Metropolitan Asylums hospitals, which had been 51, 46, and 32 at the end of the three preceding weeks, had further declined to 21 at the end of last week; no new case was admitted during the week, the numbers in the three preceding weeks having been six, seven, and two. The number of scarlet fever cases in these hospitals and in the London Fever Hospital on Saturday last, August 13th, was 1763, against 1754, 1784, and 1758 on the three preceding Saturdays; 189 new cases were admitted during the week, against 234, 243, and 166 in the three preceding weeks. The deaths in London referred to pneumonia and diseases of the respiratory system, which had been 120, 118, and 112 in the three preceding weeks, rose again last week to 121, but were slightly below the number in the corresponding period of last year. The causes of 51, or 0·8 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Salford, Bradford, Hull, and in 51 other smaller towns; the largest proportions of uncertified deaths were registered in Ipswich, Birmingham, Smethwick, Liverpool, St. Helens, Manchester, Middlesbrough, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 14·1, 14·1 and 14·6 per 1000 in the three preceding weeks, further increased to 15·7 per 1000 during the week ending August 13th, but was 6·4 per 1000 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 8·1 in Paisley and 12·3 in Perth, to 15·6 in

Aberdeen and 17 4 in Glasgow The 519 deaths in these towns included 68 from diarrhœa, 26 from whooping cough, six from measles, five from diphtheria, two from scarlet fever and two from "fever," but not any from small pox In all, 109 deaths resulted from these principal infectious diseases last week, against 68, 58, and 85 in the three preceding weeks These 109 deaths were equal to an annual rate of 3 3 per 1000, which was 6 0 per 1000 below the mean rate last week from the same diseases in the 76 large English towns The fatal cases of diarrhœa, which had been 23, 24, and 48 in the three preceding weeks, further rose last week to 68, of which 50 occurred in Glasgow, eight in Dundee, four in Aberdeen, two in Edinburgh, and two in Greenock The deaths from whooping-cough, which had been 22 19, and 26 in the three preceding weeks, were again 26 last week, and included 17 in Glasgow, five in Edinburgh, two in Paisley, and two in Leith The fatal cases of measles which had been 12, seven, and five in the three preceding weeks rose again last week to six of which two were registered in Glasgow and two in Edinburgh The deaths from diphtheria, which had been two in each of the two preceding weeks increased to five last week, and included three in Glasgow The deaths referred to diseases of the respiratory organs in these towns, which had been 75 55, and 47 in the three preceding weeks, further declined last week to 39, and were considerably below the number in the corresponding period of last year The causes of 13, or nearly 3 per cent, of the deaths registered in these eight towns last week were not certified

HEALTH OF DUBLIN

The death-rate in Dublin, which had been 17 5, 17 9, and 21 2 per 1000 in the three preceding weeks, further *rose to 27 0 per 1000 during the week ending August 13th* During the past four weeks the death rate has averaged 20 9 per 1000, the rates during the same period being 18 0 in London and 13 7 in Edinburgh The 196 deaths of persons belonging to Dublin registered during the week under notice were 42 in excess of the number in the preceding week and included 46 which were referred to the principal infectious diseases, against 15, 12 and 25 in the three preceding weeks, of these, 33 resulted *from* diarrhœa, five *from measles four from whooping* cough, two from diphtheria, one from scarlet fever and one from "fever" but not any from small pox These 46 deaths were equal to an annual rate of 6 3 per 1000, the death rates last week from the same diseases being 8 6 in London and 1 9 in Edinburgh The fatal cases of diarrhœa, which had been four and 15 in the two preceding weeks, further rose last week to 33 The deaths from measles, which had *been five, four, and three in the three preceding weeks* increased again to five last week The four fatal cases of whooping cough corresponded with the number in the preceding week The 196 deaths in Dublin last week included 69 among children under one year of age and 36 among [illegible] infants [illegible] while [illegible] nquest cases and three deaths from violence were registered, and 58, or nearly a third, of the deaths occurred in public institutions The causes of seven or nearly 4 per cent, of the deaths in Dublin last week were not certified

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE following [illegible] geons M P Jones to the [illegible] 1904), and C C Macmilla[illegible]

ROYAL NAVAL VOLUNTEER RESERVE

The undermentioned has been appointed Lieutenant Robert Roxburgh (dated August 11th, 1904)

ROYAL ARMY MEDICAL CORPS

Colonel R Blood retires on retired pay (dated August 13th 1904) Lieutenant S C Bowle, from the Seconded List to be Lieutenant (dated August 1st, 1904) Lieutenant W B Taylor resigns his commission (dated August 10th, 1904)

Captain F H M Clarke, C M G, D S O, and Captain E C Hayes join the Home District for duty Captain S W Sweetnam is posted to the Station Hospital, Colchester, for duty Major J C Weir, sanitary officer of the Home District, is directed to investigate the cause of diphtheria among troops at the Guards' Depôt, Caterham

ARMY MEDICAL RESERVE OF OFFICERS

Surgeon Major A D Fraser to be Surgeon Lieutenant-Colonel (dated August 2nd, 1904)

VOLUNTEER CORPS

Rifle 4th Volunteer Battalion the King's (Liverpool Regiment) Arthur Price, late Surgeon, Royal Naval Artillery Volunteers, to be Surgeon Captain (dated August 13th, 1904) 5th (The Hay Tor) Volunteer Battalion the Devonshire Regiment Surgeon Lieutenant W J Stephens resigns his commission (dated August 13th, 1904) 3rd Volunteer Battalion the Royal Welsh Fusiliers Surgeon Lieutenant J R Williams to be Surgeon Captain (dated August 13th, 1904) 3rd Volunteer Battalion the South Wales Borderers Surgeon Major J R Essex to be Surgeon Lieutenant Colonel (dated August 13th, 1904)

VOLUNTEER OFFICERS' DECORATION

The King has conferred the Volunteer Officers Decoration upon the undermentioned officers of the Volunteer Force — *Home District Rifle* 18th Middlesex Rifle Corps Surgeon Major Clement Godson *South Eastern District Artillery* 2nd Sussex Royal Garrison Artillery (Volunteers) Surgeon Major Henry Habgood *Scottish District Rifle* 5th (Glasgow Highland) Volunteer Battalion the Highland Light Infantry Surgeon Major George Bell Todd

DEATHS IN THE SERVICES

Major John Henry Greenway, R A M C, on August 8th, at Wynberg Camp Cape Town He entered the service in 1885 and reached the rank of Major in 1897 During the South African war he served in the Orange River Colony

THE NEW ARMY SCHEME

We make no apology for again referring to Mr Arnold Forster's new army scheme because of the far reaching organic changes it introduces the nature and effect of which the nation does not seem wholly to have grasped and understood Such should certainly be the case before finally committing itself to carry them out The general principles laid down by the War Minister will commend themselves to everyone To reduce expenditure, to maintain a regular army mainly for service abroad and ready for war, to diminish numbers at home, and to improve generally the quality of our *troops by lopping off, as far as* practicable all inefficient and redundant material are unquestionably excellent ideas and aims But when we pass from the abstract to the concrete and have to formulate the methods in detail it becomes another and much more difficult matter The net result of the scheme shows a saving of something over a million only, and this has to be obtained at a big reduction of the forces at command Mr Arnold Forster is very enthusiastic as to the success of his scheme and in cooperation with the Army Council will no doubt do all he can to carry it out He thinks that by the additional attractiveness of the service and the improvement sanitary and social, of barrack buildings, and by adding to the soldier's comfort, the necessary number of recruits of the requisite age and physical quality will be forthcoming for the maintenance of a nine years foreign service army But this is a matter which has still to be put to the test of experience At what age is the soldier to be sent to India and abroad ? That is an important medical question Some misgiving is felt, too, about the newly proposed *military depot sy tem which will probably* prove an expensive item

SOLDIERS HOMES NEAR BATH

The Bishop of Bath and Wells on August 6th formally opened two homes for men of the Royal Horse and Field Artillery, which have been erected at Claverton near Bath The homes are the gift of Mrs and Miss Fordyce Buchan, in memory of Captain G Fordyce Buchan R F A who died from *enteric fever at Bloemfontein* May 21st, 1900 The bishop, in the course of his speech, recalled the incident how, when Captain Buchan was going to the war in South Africa on board ship inoculation was recommended as a protection against enteric fever. When the operation was being performed it was found that there was not sufficient serum for all to be inoculated. Captain Buchan said that he would go without it. The others were all operated upon and none of them died from enteric fever. Captain Buchan, however, who was not inoculated, died from enteric fever at Bloemfontein, the bishop adding that his unselfishness had practically caused his death.

THE WAR IN THE FAR EAST.

In the great naval actions which have recently taken place the Russians have been badly defeated and whatever considerations they may have had for their own escape and safety or whatever strategical or other purposes they may have had in view with the Port Arthur and Vladivostok squadrons they have failed to accomplish them. As regards the siege of Port Arthur a general assault on the part of the Japanese has begun and as their troops are in overwhelming force and occupy commanding positions its fate seems to be sealed; and lastly, the position of General Kuropatkin's force is still a perilous one, menaced as it is by the surrounding Japanese armies. The rains have again returned with the result of impeding all land operations and probably of increasing the sickness on both sides. It goes without saying that with the Russian naval disasters in the Pacific it is extremely unlikely that any fleet from the Baltic, should one even have started, can reach its destination before Port Arthur has fallen. The capture of that fortress, while inflicting a very heavy blow on Russian prestige in the East (nothing has probably happened like it since the fall of Sebastopol), will liberate to a great extent the besieging Japanese forces in that direction and enable them to take part in the military operations going on elsewhere. The losses in men and money entailed by this war have been deplorable and enormous. Whether Russia will continue to prosecute it to the end, hoping to break down her enemy by weight of numbers and finance, or whether the Czar, influenced by the auspicious birth of a son and other State considerations, may seek some means of peace, no one can say. We are glad to notice, in the meantime, that the far-seeing rulers of Japan have apparently sought to do what they could in the mitigation of the horrors of the siege by offers for the removal of all non-combatants from Port Arthur, while on the occasion of the sinking of the *Ruric* the Japanese squadron hastened to rescue the drowning Russians, of whom they picked up about 600. But little is forthcoming in regard to the purely medical news of the war. It has been stated that there are many thousand sick and wounded inside Port Arthur accommodated in the various public buildings, all of which have been utilised as hospitals, but such statements rest upon mere hearsay and conjecture. It may, nevertheless, be safely assumed that there must be a large number of unfortunate sufferers inside the besieged garrison. According to the latest Russian official returns the losses of the Port Arthur garrison during the fighting between August 8th and 10th were: Killed, seven officers and 248 men; wounded, 35 officers and 1653 men; missing, one officer and 83 men.

The *Standard* of August 10th contains a long and interesting communication from its special correspondent headed "Cruise of the *Manshu Maru*" and dated June 18th. While at Sasebo he was able to see the arrangements made for transporting the sick and wounded from the fleet to the base hospital. A passenger vessel has been turned into a hospital ship for this purpose, the saloons fitted up with swinging cots, and the cabins used as operating and dressing rooms. The ship is manned by seven surgeons and 50 nurses, and as the vessel only accommodates 180 patients it will be seen what great importance the Japanese attach to female nurses, there being one nurse to every three or four patients. The ship can make the voyage to the fleet and back in about five or six days. Admiral Togo's fleet has, up to the present, been singularly free from serious sickness. There have been a few cases of enteric fever, while pleurisy has been responsible for most of the other invalids. Pleurisy is a disease the Japanese are somewhat prone to. The base hospital at Sasebo at present contains 305 patients, mostly sick or wounded by shell fire. Since the commencement of the war only seven deaths have occurred among those admitted into hospital.

The health of the troops of the first Japanese army, despite reports to the contrary, is stated to be excellent. They are not suffering from any febrile infectious disease and there is possibly less mortality or disease among them than in any army that has previously taken the field.

RUSSIAN MEDICAL STUDENTS: REDUCTION IN THE NUMBER OF CANDIDATES.

The list of applications just closed for enrolment as students in the Imperial Military Medical Academy numbers about 500, or some 300 less than last year. The *Novoe Vremya* says the results of the examinations for admission will be known in the latter half of August.

Correspondence.

"Audi alteram partem."

CONTRACT PRACTICE.

To the Editors of THE LANCET.

SIRS,—We have not yet arrived at a solution of the difficulty arising when a dispute occurs between medical men and their patients in contract practice; first, as to how we can keep away those who are ready to take advantage of any dispute; and next, when a medical man has come into a district to take up the practice at a lower rate, what shall be the proper way of dealing with such an individual. In short, we want some method of properly dealing with a man who takes up the position of a "blackleg." The warning notices put in THE LANCET and those put in the lay papers by our medical union have to a certain extent been useful, but they have not stopped all those who are indifferent to the stigma of "blackleg." And when the "blackleg" is duly installed in a district it is extremely difficult to get him out of that position. A few have been persuaded to relinquish the ill-gotten appointment; some have developed such weakness of character that their presence has shown up the righteous position of the old practitioner. Boycotting is generally carried out but it does not cause the offender to leave the district. In most cases the "blackleg" obtains his position through the canvassing of a committee of working men who do this work freely and with energy.

The General Medical Council has passed a resolution condemning any medical man who shall take up such a position and against whom the charge of canvassing can be satisfactorily proved. This is the point where we meet with our difficulty in such cases. Although we know that canvassing is done by agents on behalf of the intruder, yet it is extremely difficult to obtain the proof that is essential and to satisfy the General Medical Council. The secretaries of the County of Durham Medical Union have been in correspondence with the General Medical Council with a view to get help from that quarter, proposing the attendance of a deputation from this union to discuss the point, but we can make no progress towards accomplishing anything. Now we turn to the profession as a whole and ask as many practitioners as possible to put their names to a petition to the General Medical Council urging "upon the Council the desirability of supporting medical men who struggle to maintain the honour and dignity of the profession, especially when opposed by others who are ready to take advantage of any dispute in contract practice by canvassing or underselling, or in the obtaining of contract appointments by similar means." Copies of this petition may be obtained from Messrs. Graham and Shepherd, 32, John-street, Sunderland, secretaries to the County of Durham Medical Union.

I am, Sirs, yours faithfully,
EDWARD JEPSON,
President, County of Durham Medical Union.
Durham, August 11th, 1904.

TRANSMISSIBILITY OF PLAGUE TO THE MONGOOSE.

To the Editors of THE LANCET.

SIRS,—At a well-attended meeting of the Epidemiological Society on Nov. 20th, 1903, to hear Dr. W. J. Simpson's paper on the Epidemiology of Plague (an account of which was published in THE LANCET of Nov 28th, 1903, p 1506), Mr B G Corney (Fiji) inquired whether mongooses suffered from plague He mentioned that the matter was of some importance because some of the Colonial islands had *imported ichneumons to kill off the rats None of us* were able to answer his question, though we told him that ferrets and many other animals were susceptible and therefore probably mongooses were not immune On consulting the report of the German Plague Commission, I see that one ichneumon died from characteristic plague six days after it was subcutaneously inoculated on the hind leg Another ichneumon was fed with the organs (containing many bacilli) of a rat which had died from plague, the animal succumbed to plague five days later, being apparently infected through the mucous membrane of the mouth, not from the stomach Again in Nothnagel's Encyclopædia (Band I) in the article "Die Pest von Muller und Poch Ichneumonratten (Herpestes griseus) were experimented on Though feeding these animals with plague bacilli did not produce plague, they died after intraperitoneal infection and the post mortem appearances were those of septicæmic plague I think it must be assumed that a mongoose is a dangerous animal to introduce into any colony affected, or likely to be affected by *human plague The mongooses in Egypt live chiefly in* the desert, and therefore there is no evidence as yet of their having been attacked by plague

THE NATURE AND ETIOLOGY OF CANCER

To the Editors of THE LANCET

SIRS,—Your leading article in THE LANCET of August 13th, p 473, headed "The Nature and Etiology of Cancer,' will be read by everyone interested in that question with great appreciation of its temperate and most careful analysis and of its fulness of home truths The concluding sentences are entitled to special weight The article says Let those who in future essay to advance our knowledge of cancer regard it as their first duty to add *new facts* to those long known They may be more difficult to find than new explanations of the old ones but their accumulation will assuredly point somewhere much more definitely than the too many explanations of the old facts have done

More than 20 years ago I ventured to say in a preface to an essay on Cancer that I would point to the discussion on cancer at the Pathological Society of London in 1874 to show how unsatisfactory the then state of our knowledge was that there was a want of well ascertained facts and that the opportunity of contributing facts of great interest in relation to cancer must fall to almost *every practitioner* It is to be hoped that your article will stimulate the contribution of the facts which are so much needed Fortunately, at the present time there now exist centres of investigation to which contributions can be sent

PARALYSIS FROM LESION OF THE UPPER PART OF THE BRACHIAL PLEXUS

To the Editors of THE LANCET

SIRS —In a note on this subject published in THE LANCET of August 13th, p 447 I described two cases in which as the result of injury the deltoid, biceps brachialis anticus and supinator longus were paralysed (as in Erb's paralysis) but in addition there was paralysis of the triceps and extensors of the wrist and fingers I suggested that the cause of this form of paralysis might be lesion of the seventh cervical nerve root in addition to lesion of the fifth and sixth roots and that the lesion might affect the upper cord of the brachial plexus (formed by the union of these three roots) or the roots before their union Since the report of these cases was sent to THE LANCET Dr Wilfred Harris has drawn attention to the anatomical abnormalities in the composition of the nerve trunks of the plexus—the 'prefixed and postfixed type
the brachial plexus He points out that 'the
plexus may be therefore, shifted up or down as
as nearly half a root and this anatomical variation is of great importance in the diagnosis of nerve root lesion" (see report of proceedings of the Neurological Society, *Brain*, 1903, pp 613-15) In any case of paralysis of the arm of the form which I described it would, of course, be impossible to *say without post mortem examination whether the paralysis* was due to lesion of the fifth, sixth, and seventh nerve roots (united or separate), or whether the case was one of lesion of the fifth and sixth roots only, in a prefixed type of brachial plexus The latter would be a possible explanation in addition to the one which I have mentioned in my report

MEMORIAL TO SIR THOMAS BROWNE, M D

To the Editors of THE LANCET

SIRS,—The Sir Thomas Browne Memorial Committee has commissioned Mr Henry Pegram, A R A, to prepare the statue which is to be erected at Norwich in memory of the famous author of the "Religio Medici' Mr Pegram contributed to this year's Academy 'Sibylla Fatidica,' which has been bought for the Tate Gallery by the President and Council of the Academy as trustees of the Chantrey bequest *A few more pounds are still required to complete the neces*sary funds and contributions may be sent either to me, at King street House, Norwich, or to the Sir Thomas Browne Memorial Account" at Messrs Barclay and Co's Bank, Norwich —I am Sirs, yours faithfully,
August 12th 1904 F R EATON Honorary Secretary

THE VALUE OF THE ADDITION OF CITRATE OF SODA TO COW'S MILK IN INFANT FEEDING

To the Editors of THE LANCET

SIRS —Dr *F J Poynton's instructive* paper on the Value of the Addition of Citrate of Soda to Cow's Milk in Infant Feeding in THE LANCET of August 13th, p 433, leads me to add my testimony to the great usefulness of this simple expedient Since reading Dr A E Wright's suggestion '*On the Possible Advantages of Employing Decalcified Milk* in the Feeding of Infants and Invalids' in THE LANCET of July 22nd, 1893 I have constantly ordered the addition of citrate of soda for persons who could not otherwise take milk Dr Wright in his original paper says that an addition to milk of 1 in 200 of citrate of soda suffices to prevent any rennet coagulation As a
from seven to nine ounce
one gramme of citrate of
the right proportion This decalcified milk has in my experience been always well borne by persons who had previously been upset by milk In typhoid fever it forms an ideal nourishment

I am, Sirs yours faithfully,

A MINISTRY OF PUBLIC HEALTH

To the Editors of THE LANCET

SIRS —The medical profession is consistently educating the public in the value that should be attached to State medicine and the need for a definite national or State 'policy in its favour In August, 1904 the following resolutions have been passed —

1 The Royal Institute of Public Health at Folkestone advocated a Ministry of Health and recommended that the subject should be made an official one in the programmes of all international or national health congresses

2 The Oxford meeting of the British Medical Association desired that a Royal Commission be appointed to report upon the suggested reorganisation of the Local Government Board, the principles of which were defined in a memorandum to the Medico Political and Public Health Committees

3 The Interdepartmental Committee on Physical Deteriora
recommendations reported on the
advisory council This would
ll legislative and administrative
points concerning the public health and would receive and

apply the information derived from the proposed Bureau of the Anthropometric Survey with the whole weight of Government authority and scientific prestige behind it.

4. Sir Lauder Brunton is forming the National League for Physical Education and Improvement, embracing a comprehensive educational scheme.

Undoubtedly, however, one of the strongest educational agencies would be a strenuous expert Minister of Health of Cabinet rank. Such an appointment has been approved at congresses at Exeter in 1902 and at Bradford, Swansea, and Brussels in 1903. May I be allowed to repeat the outlines of a Ministry based on the War Office Reorganisation scheme at this opportunity? They are, in brief, an advisory committee, an administrative council, an increased inspecting staff, and an extended sanitary and pathological service. The keystone of the fabric is, however, a leader in the person of a Minister and I venture to urge that the British Medical Association and the National League for Physical Education make this the focus of their aspirations. In consideration of the increasing numbers and the reputation of those of our profession interested in this organisation of State medicine it appears only necessary to imbue the laity with similar sentiments through the branches of the British Medical Association and other agencies.

I am, Sirs, yours faithfully,
F. G. BUSHNELL, M.D.,
Pathologist to the Sussex County Hospital.
Brighton, August 13th, 1904.

THE USE OF PHENYLHYDRAZIN IN THE CLINICAL EXAMINATION OF URINE.

To the Editors of THE LANCET.

SIRS,—I am afraid that Dr. A. F. Bilderbeck Gomess has not realised the reason for which my paper was written on the Use of Phenylhydrazin in the Clinical Examination of Urine.[1] I am in entire agreement with Dr. Gomess on the value of phenylhydrazin in the clinical examination of urine and, as he suggests, the reagent should be applied to the urine directly and not after previous hydrolysis by boiling with hydrochloric acid. In this case the test is of the greatest value in the detection of sugar in a diabetic urine and as I pointed out in my paper normal urines do not give characteristic crystals. I regard the phenylhydrazin test as applied directly to a urine of greater value than the Fehling's test and many of the other tests used for the detection of sugar in urine. The object of my paper was to point out that the production of crystals from a urine which had been previously hydrolysed by boiling with hydrochloric acid was not of any pathological significance, since, as I have proved, normal urines give very characteristic crystals with phenylhydrazin after treatment in this way. It has recently been stated that the production of crystals in a urine on treatment with phenylhydrazin after previous hydrolysis is an indication of disease of the pancreas, and the object of my paper was to point out that this reaction is given equally well with normal urines and cannot, therefore, be regarded as an indication of pancreatic disease.

I am, Sirs, yours faithfully,
August 15th, 1904. W. H. WILLCOX.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Small-pox in Dublin.

AT a special meeting of the public health committee held in the municipal buildings on August 10th, Sir Charles A. Cameron reported that three cases of small-pox had occurred in Dublin and had been conveyed to the isolation hospital. He added that on no previous occasion was the department so well prepared as at present to resist the spread of small-pox on its first appearance. He said, moreover, that there was every reason to believe that this small outbreak would be stamped out at once. There were no additional cases up to August 16th.

Portrush Cottage Hospital.

A bazaar was opened in the town hall, Portrush, co. Antrim, on August 9th for the furnishing and equipment of the Cottage Hospital, the starting of which is due to the efforts of a local lady, Miss Reynolds. The Provost of Trinity College, Dublin (Dr. Traill) presided and delivered an interesting address on the value and importance of hospitals.

Police Appointment.

Dr. Alexander Montgomery has been appointed medical attendant to the Royal Irish Constabulary in O District of Belfast in succession to Dr. W. M. Killen, resigned. There were 25 candidates.

Small-pox in Ulster.

This disease, which was introduced from Glasgow into Belfast, has spread in different directions over Ulster, the last place for it to appear being in Monaghan where there have been two cases, one of which, a girl, has died. 15 cases are being treated in Castleblayney workhouse fever hospital from Crossmaglen.

Appointment for a Belfast Medical Professor.

Dr. J. Lorrain Smith, Musgrave professor of pathology, Queen's College, Belfast, has been appointed joint lecturer in the same subject in the Victoria University, Manchester. Professor S. Delépine is to take the public health portion of the chair and Professor Smith is to have the pure pathology. Dr. Thomas Houston of Belfast will be a candidate for the chair thus vacated at Queen's College. He has been an assistant to Professor Smith, is a research scholar of the British Medical Association, and he held the pathological studentship in the Royal University. He has done considerable original work and is at present joint lecturer on medical jurisprudence with Professor Smith.

Queen's College, Belfast.

The report of the president of Queen's College, Belfast, for the session 1903–04 shows that in the Faculty of Medicine there was an increase in the number of entrances; indeed, the entrances at Queen's College, Belfast, were higher than those in any other medical school in Ireland with the exception of the Catholic University School of Medicine, Dublin, which shows an entrance of three more students. There is also an increase in the law and engineering faculties. Deep regret is expressed at the continued refusal of the Government to subsidise to a fuller extent the College, which is a Crown one, and still more as the public have subscribed nearly £100,000 for its equipment.

Health of Belfast.

From June 19th until July 16th 12 cases of small-pox have been notified and since the outbreak in October last 102 persons have been admitted into the small-pox hospital, of whom 75 were discharged cured, three died, and there were still 24 in the hospital, while 328 "contacts" passed through the intercepting hospital and 61 remained under observation. Not an individual who has been revaccinated has been admitted into the small-pox hospital. At present Belfast is comparatively free from infectious disease, the number of cases of scarlet fever being much fewer than for a considerable time, as also are those of typhoid fever. The annual death-rate in Belfast was 17·3 for the past four weeks.

August 16th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Surgical Treatment of Acute Hepatitis.

AT the meeting of the Society of Surgery held on July 27th M. K. J. L. Faure read a paper sent in by M. Denis of Constantinople. It dealt with the case of a sailor who showed symptoms of acute hepatic infection—viz., jaundice, fever, hypochondriac pain, and enlarged liver. M. Denis opened the abdominal cavity and found the liver much enlarged and congested. He punctured the liver in various places without result for he found no pus. He then closed the abdomen and to his great astonishment the temperature fell and never rose again and the patient recovered completely. The result in this case may be compared with many others previously sent in by various observers. Recovery has often taken place after simple laparotomy, together with exploratory puncture, and in some cases the patient has recovered after laparotomy alone. At the same meeting M. Lejars gave an account of the case of a woman who had been admitted to the hospital in a very serious condition She was extremely thin, slightly jaundiced and her liver was enlarged Laparotomy was performed and M Lejars found a tumour, continuous with the liver, of a yellowish grey colour and of a woody consistency M Lejars did nothing further believing that he had to deal with a new growth, and closed the abdomen To his great astonishment the patient began to improve and at the end of a few months the tumour had entirely disappeared Ten years later however, a gummatous swelling appeared on the tibia which yielded to antisyphilitic treatment The tumour of the liver was doubtless a gumma but it disappeared without any other treatment except the simple laparotomy Various other speakers at the meeting related cases confirming the results in the two cases mentioned above

[1] THE LANCET, July 23rd, 1904, p. 211.

The Sale of a Medical Practice

Questions as to the sale of a practice often arise and are the source of much discussion and very often of legal proceedings Jurists, however, have little by little arrived at certain definite canons which must be observed in such circumstances As a legal principle, the simple sale of a practice—that is to say, when nothing is transferred except the trust and the willingness of the patients to be transferred from one medical man to another—has no legal value whatever, but the sale of a practice is recognised as being of definite legal value when at the same time as the patients are transferred other objects are handed over—for instance, personal effects instruments, and medical books, the transfer of the lease of a consulting room An engagement on the part of the vendor to introduce the buyer to his patients, or a bond by the vendor not to practise within a certain definite radius of his old sphere of work, also make the transaction a genuinely legal one Another point has just been decided—viz , Is the transfer of a practice of equal legal value when the sale is carried on not by the actual practitioner himself but by his widow or by his heirs? Recently a medical man bought the practice of a deceased brother practitioner and after the contract had been signed he refused to execute it because in the meantime he had found what he considered a better opening in another town, and when the widow of the deceased practitioner asked for damages he pleaded that the contract of the sale was of no legal value The matter came before the courts and the tribunal gave judgment in favour of the medical man, but the Court of Appeal reversed this decision and granted the widow the damages which she demanded giving as reasons for this judgment that the sale of the practice included articles of furniture the lease of a consulting room, and an engagement to give a personal introduction to the patients

Psychotherapy and Hysteria

At a meeting of the Academy of Medicine held on July 16th M Janet described some abnormal psychological conditions presented by a young girl who had become hysterical through grief for the death of her mother While suffering from delirium hallucinations, and hysterical attacks she had an unusually full recollection of the death and of all the circumstances associated with it, but in the lucid intervals when her state might be regarded as normal she had almost no recollection of the very events in question and appeared to look on her mother s death as a very trivial matter There were therefore hypermnesia during the attacks and amnesia during the intervals between the attacks M Janet has observed several similar cases He commenced by "re educating the memory of the patient and this being accomplished the phenomena of hypermnesia and hallucination disappeared M Janet then called attention to the importance and value of psychotherapy provided always that it be applied in the proper degree and judiciously employed in suitable cases

Use of an Artificial Larynx after Laryngectomy

At a meeting of the Surgical Society held on July 20th M Sébileau reported a case of cancer of the larynx in which he had performed an operation similar to that of Périer Recovery was rapid and the scar in the neck was quite sound To replace the larynx the choice lay between Gluck s artificial larynx, which was a modification of a tracheotomy tube, and Martin s artificial larynx which was not applicable in the present instance as the skin had to be brought over it and an extensive operation would have been necessary in order that it might be placed in position M Sébileau therefore asked M Deler, instructor in prosthetics at the Dental School, to make a special pattern of the larynx The apparatus constructed by M Deler consisted (1) of a rectangular box attached in front of the cannula worn by the patient and having a valve which permitted inspiration but not expiration , and (2) of a portion contained within the mouth corresponding to the palate and glottis The result was very good and the patient could make himself understood quite well, although the tone was decidedly different from that of the natural voice

Intra-articular Osteotomy for Ankylosis of the Knee joint

At the same meeting of the Surgical Society M Broca described a case under the care of M Guillon of La Tremblade The patient was a boy 12 years of age, who suffered from osseous ankylosis of the knee joint the effect of an injury M Guillon performed intra articular osteotomy and obtained a good result as appeared from a photograph which was shown These cases of special osteotomy are rare, but one in the elbow has been already reported to the Surgical Society M Broca said that M Guillon had placed the limb after the operation in a position of semiflexion Although the result was good this position was hardly to be recommended

August 15th

NEW YORK

(FROM OUR OWN CORRESPONDENT)

Resignation of Dr Shrady

Dr George F Shrady who for more than 38 years has been the editor of the *New York Medical Record* has just resigned that position Dr Shrady has occupied a unique place in American medical journalism, in fact with the exception of the first Mr Wakley of THE LANCET, no editor of a medical journal published in English has held a like position for so long a period There have also been points of similarity between the editorial careers of the American and English medical editors Dr Shrady brought the journal of which he was editor from an insignificant sheet to a place in the front rank of American medical journalism In addition to his executive abilities and courage Dr Shrady in his editorial capacity was possessed of both tact and a remarkable gift of seizing upon salient points of medical policy and presenting them clothed in forcible expressive, and attractive phraseology Above all, he has been a staunch and true friend to the medical man has studied his interests advocated his cause, and fought to redress his wrongs with the most unselfish zeal He has left a decided mark upon American medical journalism Dr Thomas L Stedman the former associate editor of the *Medical Record* who has assisted Dr Shrady in the management of the journal for some 20 years, now becomes editor-in chief

Suicide in New York City

There has been a decided tendency towards increase in the number of suicides in New York city Records of the Police Department and of the Health Board show that during the first quarter of the current year 208 individuals took their own lives It is further computed that the number of suicides for the year will be more than 900 This year 224 out of 1 000 000 will have put an end to themselves, the annual ratios for the four preceding years having been 215 187 206 and 150 Of 806 persons who committed suicide in New York city last year 35 per cent were native born 26 per cent were German, 7 per cent were Irish, 5 per cent were Russian 5 per cent were Austrian, and 3 per cent were English Poisoning was the most common mode of suicide, about 47 per cent choosing this method of ending existence Carbolic acid was by far the most favourite poison used 20 per cent sought death by shooting, 16 per cent used illuminating gas for the purpose, while 8 per cent resorted to hanging

The Laboratory of the Rockefeller Institute

The building of the laboratory of the Rockefeller Institute of Medical Research is about to be commenced The edifice will be placed on Exterior street, east of Avenue A It is to be a five storey building 136 feet front with a pilastered façade of limestone and ornamental brick The upper storeys are to be furnished as general and special laboratories and research rooms and the roof will have houses for the animals An auditorium hall, library, and study will be on the first floor, while an annex will contain a two storey building for the animals and a power house

[1] THE LANCET, July 23rd, 1904, p. 211.

SIR WILLIAM MITCHELL BANKS,
CONSULTING SURGEON TO THE LIVERPOOL ROYAL INFIRMARY AND EMERITUS PROFESSOR OF ANATOMY IN THE UNIVERSITY OF LIVERPOOL.

DR. T. GILBART-SMITH,
PHYSICIAN TO THE LONDON HOSPITAL AND TO THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

SIR FREDERIC BATEMAN
CONSULTING PHYSICIAN TO THE NORFOLK AND NORWICH HOSPITAL AND TO THE EASTERN COUNTIES ASYLUM

Fellowship without a hitch From 16 years' experience on the Council and its committees I should say this incident in the history of the professional examinations of the College was a unique one Both in the dissecting room as a demonstrator and subsequently in the anatomical theatre Sir William Banks was seen to great advantage He spent an immense amount of time in making a most excellent and comprehensive collection of diagrams (many of them quite works of art) and anatomical preparations (of his own dissections) for the instruction *of his class He had a great belief in giving his students* not only a discourse but something to look at He rarely published a surgical paper without introducing one or more original illustrations He believed in teaching by the eye as well as by the ear concurrently His dissecting room aptitude and his method of displaying it proved of great service to him when he became assistant surgeon and subsequently surgeon and lecturer on clinical surgery at the Royal Infirmary Some of his operations which required in particular accurate and extensive dissection—for instance, the removal of growths and tumours about the neck and the ligature of large arteries in connexion with aneurysms—were models of execution and at the same time demonstrated the breadth and utility of his experience as an anatomist He was an excellent colleague at the bedside of either a hospital or private patient and never spared himself to help whoever was associated with him in the most loyal and disinterested manner Like many men of decision he had strong likings and dislikings and did not hesitate to say so even at the risk of giving offence in high quarters It *may* be *truly said of* him that he had the courage of his convictions

THOMAS GILBART SMITH, M A , M D DUB , F R C P LOND ,

PHYSICIAN TO THE LONDON HOSPITAL.

THE death of Dr T Gilbart Smith, which we announced last week came as a great shock to his many friends He was in the active practice of his profession and with the exception of the members of his family no one knew that his health gave cause for anxiety He was enjoying a holiday in Devonshire with one of his sons and whilst bicycling on the evening of August 3rd suddenly fell from his machine and when his son reached him life was found to be extinct Death was due to angina pectoris, the attack probably having been induced by the effort of mounting his bicycle

Dr Gilbart Smith was born in 1848 and was the son of the Rev *J Denham Smith of Dublin He* was *educated* at a school in Shropshire and then proceeded to his medical studies at Trinity College, Dublin where he graduated in 1869, *passing* the examination *for the Membership of the* Royal College of Surgeons of England two years later He took the degree of M D in 1873 He likewise studied at St Bartholomew s Hospital and at Paris He was elected a Fellow of the Royal College of Physicians of London in 1885 In 1878 he was appointed assistant physician to the London Hospital, becoming full physician in 1894 In addition to holding this appointment at the time of his death he was physician to the Royal Hospital for Diseases of the Chest City road and consulting physician to the Tottenham Hospital, to the Mildmay Park Cottage Hospital and to the Cripples Nursery He was also chairman of the hospital committee in connexion with the Mission to Deep sea Fishermen He was one of the Vice Presidents of the Medical Society of London—a society in which he had served on the council and as secretary , he was also one of the trustees of the Fothergillian Fund

Dr Gilbart-Smith was essentially a clinician He had gathered his medical knowledge from a close observance of disease as presented in actual practice at the hospitals and elsewhere He recognised that medicine was not only a science but an art and that to become a successful physician it was necessary to educate the senses in every way possible He possessed in a high degree the faculty that has been aptly termed ' clinical instinct ' and so was frequently able to arrive at a correct diagnosis more speedily than one who relied entirely on theory We may quote Corvisart s observations on the art of medicine as being particularly applicable to *Dr* Gilbart-Smith s methods and teaching in clinical work "The education of the senses is so important, so indispensable, that without it *I do not think it possible* to be a skilful physician at the bedside of the patient And what is it, in fact, which is commonly called experience in medicine, which prevails so often over the greatest erudition, the most solid information, but the result of the frequent methodical, and just exercise of the senses, whence are derived such facility in their application such readiness of appreciation, such certainty of judgment sometimes so rapid that all these acts appear to be simultaneous and the aggregate of which are comprehended under the denomination of tact? ' Dr *Gilbart Smith s lectures in class* room or ward *all* bore the stamp of original thought and practical experience and those who served under him as house physicians or clerks especially benefited by his tuition in practical work His genial Irish nature and ready wit, combined with his handsome and commanding presence, endeared him to all who knew him He was ever ready to lend a helping hand or encouraging word to a student or young practitioner just starting on his professional career Amongst the students he was immensely popular He took the greatest interest in all the various societies and clubs in connexion with the London Hospital and held office in many of them In short in every way he gave cordial support to all that appertains to the social life of the students outside their professional work and thereby greatly assisted the popularity and success of the medical school His contributions to medical literature were not many but such papers as he read before the medical and other societies were of a strictly practical type

Dr Gilbart Smith married in 1870 the daughter of Mr Thomas Bewley of Rockville co Dublin, and at once *commenced* practice in Harley street occupying until his death the same house He leaves a widow and three sons, one of whom is in the medical profession The esteem in which he was held by his colleagues and friends was demonstrated by the large attendance on the day of his funeral After a brief service at his house the interment took place at Hampstead Cemetery the body being borne to the grave by personal friends who were also representatives of the various hospitals to which he was attached The service in the cemetery was of the simplest character in accordance *with his own wishes Around the grave were gathered many* members of the London Hospital staff and committee and numerous friends belonging to the medical profession who cherished memories of acts of kindness shown to them during his life time

SIR FREDERIC BATEMAN, M D ABERD , F R C P LOND ,

CONSULTING PHYSICIAN TO THE NORFOLK AND NORWICH HOSPITAL.

SIR Frederic Bateman of Norwich, who died at his residence in that city on August 10th, had for many years been recognised as one of the foremost representatives of the medical *profession in East Anglia He had attained a great* age and the closing scene was of brief duration On August 8th he attended a meeting of the managers of the Bethel Hospital for the Insane an institution with which he had been connected for many years and resigned his position as consulting physician On the 9th he was out of doors but *in the evening he complained of illness* and he passed away in the early hours of the following morning

Sir Frederic Bateman belonged to a Norwich family and was born in 1824 his father Mr John Bateman, being sheriff of the city in 1837 His medical education was received in Paris and at University College London He obtained the French medical qualification of Officier de Santé in 1846 in 1849 he was admitted M R C S Eng and in 1850 he graduated as M D at the University of Aberdeen also in the same year taking the diploma of L S A In 1851 he was appointed house surgeon to the Norfolk and Norwich Hospital and on retiring from that position he engaged in general practice as a partner of the late Mr Gil son In 1864 on the retirement of the late Dr Ranking he became physician to the Norfolk and Norwich Hospital an appointment which he held till 1895 In 1866 he was admitted a Member of the Royal College of Physicians of London and in 1876 he was elected a Fellow In 1895, after 30 years service on the staff *of the Norfolk and Norwich Hospital he* became consulting physician He was also consulting physician to the Eastern Counties Asylum for Idiots to the Jenny Lind

Infirmary for Children, to the Norfolk and Norwich Eye Infirmary, to the Norwich City Asylum, and, as already mentioned, to the Bethel Hospital for the Insane. He was a member of a variety of medical societies, British and foreign, as well as a foreign associate of the French Academy of Medicine. His most important published work was a treatise on Aphasia which gained the Alvarenga prize of the French Academy of Medicine; the first edition, the title of which was "Aphasia, or Loss of Speech, and the Faculty of Articulate Language," appeared in 1870; the second edition, much enlarged, in which the title was changed to "Aphasia and the Localisation of the Faculty of Speech," was issued in 1890. He was also the author of "The Idiot and his Place in Creation," as well as of contributions to THE LANCET and other periodical literature of the profession. He sat in the Norwich town council for the old Third Ward and in 1872 served the office of sheriff, as his father had done before him, fulfilling the duties of the position so well that special reference to his merit in this capacity was made in the votes of thanks awarded to him at the end of his term. During his shrievalty the Social Science Congress was held in Norwich and Sir Frederic Bateman took an active part in the discussions. He read a paper to the members of the Churchman's Club on Darwinism tested by Scientific Researches in Language, declaring himself to be altogether opposed to the theories of the evolutionists. In 1892 he received the honour of knighthood. In 1893 the University of Aberdeen conferred on him the degree of LL.D.

A medical friend of Sir Frederic Bateman has sent us the following details as to some of his personal characteristics:—His special taste was for literary work and his book on "Aphasia" was the labour of the most active years of his life. He had resided in Paris and was thoroughly conversant with French medicine and its literature. He was a great linguist and, in fact, an accomplished scholar in both modern and classical languages. His work shows abundantly how deeply read he was in all that had been written on his subject. In addition to his literary and scientific work he carried on a consulting practice in Norwich and the surrounding district and his services were in requisition particularly as an expert in diseases of the brain. As a colleague he was all that could be desired and his relationship with his brother practitioners was marked by the greatest cordiality. It was felt that with his absorption in literary pursuits he was beyond the reach of any of the petty frictions that sometimes mar inter-professional relations. He was of a most kindly disposition and many of his younger colleagues owe much to his ready help.

In 1855 he married a Miss Gooderson of Norwich who died in 1897. Their surviving family consists of three sons (all of whom are in the medical profession) and two daughters. The funeral took place on August 13th at Norwich Cemetery.

(FROM OUR OWN CORRESPONDENT.)

Quarantine Conference.

A CONFERENCE of medical officers from the several States on the subject of future Federal quarantine laws has been held in Melbourne. The members of the conference were Dr. D. A. Gresswell, chairman of the Victoria Board of Public Health, who was subsequently appointed chairman; Dr. J. Ashburton Thompson, chief medical officer, New South Wales State Government; Dr. B. B. Ham, Commissioner for Public Health, Queensland; Mr. T. H. Lovegrove, principal medical officer, Western Australia; Dr. W. Ramsay Smith, chairman, Board of Health, South Australia; and Dr. Elkington, permanent head Department of Public Health, Tasmania. In a brief speech of welcome the Minister of Customs pointed out that the questions upon which he desired the experienced gentlemen before him to give advice were:—1. The advisability of taking over administration of the quarantine laws of the several States. 2. The provisions necessary or desirable to introduce in a Federal Quarantine Bill in regard to (*a*) prevention of the introduction of diseases from abroad, (*b*) the prevention of the dissemination of disease, and (*c*) the quarantine of animals and plants. And 3. Generally in regard to (*a*) method of administration, central staff, &c.; and (*b*) any matter in connexion with which it may seem Commonwealth legislation should deal with. The Cabinet would, however, like advice on all cognate matters which would suggest themselves to the conference. The information was required with as little delay as possible as the Government desired to proceed with a Bill before long. After the conference rose Dr. Gresswell said that it had been decided to issue no progress statements of the proceedings, as its work was only tentative and suggestive. The conference would need to get legal advice as to how far Federal powers extended in quarantine matters and to accummulate information as to machinery already existing in the States. Dr. Gresswell was doubtful whether the conference would draft a complete Federal Bill. The Minister of Customs would be supplied with a full report, and doubtless, as the outcome of the conference, a smaller body would be intrusted with the drafting of a Bill.

Lunacy in Victoria.

The report of the Inspector-General of Hospitals for the Insane in Victoria has been presented to Parliament. On Dec. 31st last there were 4570 persons on the registers, an increase of 23 for the 12 months. Of these 4349 were resident, 184 were on probation with friends, and 37 were under the care of guardians. There were 754 persons admitted during the year, a decrease of 30 as compared with 1902. In addition there were six persons confined in lunacy wards attached to public hospitals. No improvement had been made as regarded the arrangements for night nursing. The necessity for an increased night staff and suitable observation dormitories was emphasised. A trained female nurse had been appointed to the male hospital at the Kew Asylum and a part of the male division at the Beechworth Asylum had been staffed with female nurses. The ratio of persons admitted to the general population was 1 to 1603. The ratio for 1902 was 1 to 1537, and in 1901, 1 to 1596. There was one person registered as insane in the State for every 264 of the general population, as compared with one for 265 for the previous year. The recovery rate was 42·29 per cent., and the relieved rate 6·65. The recovery and relieved rates for 1902 were 43·48 and 6·90 per cent. respectively. The total expenditure of the department was £135,795 2*s.* 6*d.*, a reduction of £2897 0*s.* 11*d.* on the previous year. The actual cost of maintenance of patients was £131,042 15*s.* 3*d.*, and the average weekly cost of patients was 11*s.* 7*d.*, or, deducting the amount received from collections, a net cost of 9*s.* 10¾*d.* as against 10*s.* 4½*d.* for 1902. In conclusion, as this was the last report under the old system before the new Act came into operation, the inspector gave the following list of improvements effected during the last few years:—The introduction of trained female nurses, provision of spray baths, separation of the idiots, and imbeciles, provision for female criminal lunatics at Ararat, accommodation for female epileptics at Ballarat, increasing means of employment as a factor in treatment, systematic training of attendants, improvement in the food supply, adoption of observation dormitories with constant night supervision of epileptic and suicidal patients, and improved fire prevention methods.

Hospital Accommodation for Babies in Sydney.

The council of the Woman's Progressive Association of Sydney has collected the following information as to the hospital accommodation available in Sydney for sick infants under two years of age:—

The Sydney Hospital has no separate ward for sick babies or children, and has only eight cots; but the board has proposed plans for providing 16 cots when funds are available. At the Moorcliff branch very young children are treated for eye diseases. The Royal Prince Alfred Hospital has one ward of 16 cots exclusively devoted to the nursing of sick infants who are admitted from the age of a few weeks upwards. When the beds of the new pavilion are being allotted the question of giving further room for infants will be fully considered. St. Vincent's Hospital does not undertake the general treatment of sick infants. Lewisham Hospital receives sick children from 15 months to 14 years; but has not many beds for them and only admits younger babies when an operation is imperative, and then admits them at any age the doctor wishes. The Sydney Benevolent Asylum takes destitute children, sick or well, and at any age. In the new hospital a ward is being set apart for 36 sick children; mothers are also admitted. The Waitara Home receives sick infants at any age and has 12 cots set apart for them. Mothers are asked to remain with their sick babies. The Royal Alexandra Hospital rule for age admission is between 18 months and two years, but in urgent cases young children are taken into the hospital irrespective of ag[illegible] provision for sick babies the secretary state[illegible] tained in your letter are receiving serious [illegible] will allow it is hoped provision for the reception of young babies will be provided in the new hospital."

The council considered:—

1. That the existing and proposed accommodation was totally

inadequate to stem the appalling infant mortality, which was upwards of 5000 annually.

2. That the contemplated provision was chiefly for infants of 18 months and upwards, whereas the loss of infant life under that age was most disastrous, and discreditably reflected on existing conditions, in

y children, that
it was based on

nfants alone was
ed where young
ould be specially

July 11th.

Notes, Short Comments, and Answers to Correspondents.

STREET NUISANCES.

AT the last meeting of the city council of Manchester Dr. C. G. L. Skinner drew attention to some of the common, and therefore all the more objectionable, nuisances that disgrace our streets. He asked if the watch committee had observed how great and growing was the nuisance from dirty paper blowing about the streets and the danger to the community from broken bottles, principally mineral water bottles. He called the attention of the watch committee to it rather than the sanitary committee because it was a matter needing prevention more than cure. The tradesmen's errand boys are responsible for the greater part of the paper nuisance, and there ought to be some mode of impressing on them that they must not scatter waste paper broadcast. Nowadays there is so much disregard of authority that errand boys respect it no more than they would have feared the "curate" in the *Private Secretary*, when he threatened to give "a good, hard knock." The broken bottle nuisance is a danger that ought to be treated seriously but the by-laws against it are too often a dead letter. Nearly every country lane and open space accessible to the public are dangerous from the same cause.

THE FOUNDER OF "THE LANCET."

Dr. Stanley B. Atkinson, honorary secretary of the Medico-Legal Society, in reading some old articles on Medical Evidence in the Inner Temple library, recently came across the following interesting reference to the founder of THE LANCET in the *Monthly Law Magazine*, vol. viii. (1840), under the heading "The Present State and Conduct of Parties" (i.e., political), and he sends it to us thinking that we may care to add it to the archives of the history of THE LANCET.

> Mr. Wakley has a pretty vituperative manner of his own, even when he does not descend to an imitation of Mr. O'Connell, and a skill at hitting the right nail on the head that is very painful when the head chances to be endowed with a sensorium. To him we leave it to deal with such epithets as "vulgar and unfounded taunts," and "coarse and ludicrous sarcasms"; the coroner for Middlesex is just the man to tame an Edinburgh reviewer; we are content to know how bitterly and pungently the sarcasm applies, even though we have not "the equivocal merit of having invented it."—P. 58.

PRACTICE IN ONTARIO.

To the Editors of THE LANCET.

SIRS,—I am anxious to know if holders of the triple qualification of Scotland are entitled to practise in Ontario. I am told that I should be required to pass the licensing examination of that State before practising there. I understand that any British qualification entitled one to practise in the British Empire.

I am, Sirs, yours faithfully,

August 13th, 1904. L.R.C.P. & S. Edin.

*** Our correspondent will find information about practice in Canada on p. 651 of THE LANCET of Sept. 5th, 1903. In Ontario registration by the council of the College of Physicians and Surgeons of Ontario is necessary for anyone who wishes to practise and it is optional for the council to admit to registration all persons who are duly authorised to practise medicine, surgery, and midwifery in the United Kingdom and Ireland upon terms which the council may deem expedient.—ED. L.

RABBITS AS "SAND-BAGS."

To the Editors of THE LANCET.

SIRS,—A day or two ago I was called to a little boy who had broken [illegible] in a harvest field. I found the injured limb [illegible] between two freshly-killed rabbits which made [illegible] and also, as the lady who arranged them truly remarked, tended to keep the limb warm. This treatment might be quoted in support of the efficacy of "a hair of the dog that bit him."

I am, Sirs, yours faithfully,

Silverton, August 16th, 1904. O. CLAYTON-JONES, M.B. Oxon.

THE SPREAD OF SMALL-POX.

A WOMAN named Clara Powell was recently summoned at Lincoln for exposing a child in her charge suffering from small-pox without taking proper precautions to prevent the spread of the disease on July 30th. The deputy town clerk (Mr. T. W. Page) appeared to prosecute on behalf of the sanitary authority. The defendant, he said, was in receipt of relief from the board of guardians for the purpose of supporting a child named George Barty, 12 years of age. On July 30th the sanitary inspector saw the child and found him to be suffering from small-pox in the early stage of the disease. He had the child taken home in the ambulance van and distinctly told the defendant that he was suffering from small-pox and was in no circumstances to be allowed to leave the house. On the evening of the same day, however, the child was found selling matches in the smoke-room of a licensed house. The offence could be made an indictable one but the sanitary authority had proceeded under the Public Health Act, under which the penalty was £5. The defendant admitted the offence and was fined the full penalty of £5, the alternative being to go to prison for a month. 14 days were allowed for payment. This story is a striking example of how careless, ignorant, or wilful people may damage the community for the sake of a few halfpence of profit, and further the futility of relying upon the obedience of such people instead of at once removing the patient to an isolation hospital.

AN APPEAL ON BEHALF OF MISS E. B. PELLATT, L.S.A.

To the Editors of THE LANCET.

SIRS,—May I enlist your kind help in bringing the following facts to the notice of the readers of THE LANCET? Miss E. B. Pellatt, L.S.A., who became qualified in 1893, decided in 1895 to take up the work of a medical missionary. She was a member of the Guild of St. Luke and having studied Arabic at Zanzibar joined the St. Philip's mission at Cape Town under the Society of St. John the Evangelist in 1896. Here she worked until February, 1903, when she was compelled to return to England on account of her health, but hoping to be able to return to work in December. Optic neuritis of both eyes, however, set in and in February of the current year she was completely blind of the right eye and had but little more than perception of light in the left. She is thus shut out from following her profession, her family are unable to help her, and the sphere of work for her gaining a livelihood by her own efforts must be very limited. It is therefore hoped that her professional brothers and sisters will do what they can to help her. Contributions may be sent to Colonel Francis H. Welch, F.R.C.S., 8, Brandram-road, Lee, S.E. The following have already responded to the appeal. I am, Sirs, yours faithfully,

Welbeck-street, W., August 13th, 1904. E. F. DRAKE-BROCKMAN.

A QUESTION FOR ARGUMENT.

A CORRESPONDENT under the name of "Fairplay" propounds the following hard case:—Dr. S. was a temporary assistant to Dr. B. Dr. B. in order to remove his own bicycle put Dr. S.'s bicycle close to the waiting-room door which was left open. People passing in the street could see the bicycle (Dr. S.'s) which was the best in the town. Dr. S.'s bicycle was stolen on that very day. Has Dr. S. any claim on Dr. B. from whose premises he lost his machine?

We do not suppose that the law would support Dr. S., but Dr. B. might still be held morally liable at any rate for part of the loss.

A METHOD OF REMOVAL OF THE POST-MORTEM ODOUR FROM THE HANDS.

To the Editors of THE LANCET.

SIRS,—Perhaps the following may interest some of your readers. A fortnight ago after performing a post-mortem examination I had occasion to rub my hands with chloroform to remove some rubber plaster and to my surprise found that the unpleasant smell on my hands was completely gone. I have done the same to-day after a post-mortem examination with a like result. I have tried many methods of removing the smell but I have found none so effective as this.

I am, Sirs, yours faithfully,

August 16th, 1904. HEATON C. HOWARD.

*** The method may give rise to transient irritation.—ED. L.

AN INCOME-TAX QUERY.

To the Editors of THE LANCET.

SIRS,—I am an outdoor assistant at a salary of £220 per annum—i.e., I have to pay weekly rent for rooms situated in a village one and a half miles from the house of my principal. His plate is on the gate but otherwise the house is not his. I am now asked to pay income-tax. Before coming here I was an indoor assistant—i.e., living at a branch at £160. I reckon that board and lodging here cost me £60 per annum—i.e., I am no better off than previously, but I had no income-tax to pay before. Am I now liable to be taxed on the £60? My principal no doubt claims abatement on my salary. A brief reply in your correspondence column will oblige.—I am, Sirs, yours faithfully,

A. B. C.

August 16th, 1904.

*** Yes, our correspondent must pay.—ED. L.

◆

Sophos.—Without knowing the exact duties assigned to our correspondent's office we are unable to help him very definitely. Probably the authorities consider that the treatment of persons who have fallen into the harbour is a part of his duties As to the other case in all probability the injured party is liable The whole state of matters as regards payment of medical men called by the police to see patients is most unsatisfactory In London, at any rate no compulsion rests on any medical man other than a police surgeon to answer the summons of a constable to see a patient But the police authorities will generally pay a fee of either 3*s* 6*d* or 7*s* 6*d* according as the call is in the day or the night The same fees have been recovered for similar services in various places in England But as a rule it may be said that when any medical man is called to a street accident, if he does not go he is stigmatised as inhuman and if he does go no one is liable for his fee

Monaco—Permission to practise in the principality is granted solely by favour of the Prince of Monaco Our correspondent can make an application through the Consul General in London 37, Conduit-street Bond street W

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed To the Sub Editor

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

A Presidential Address

ON

PREVENTIVE WORK IN THE TROPICS.

Delivered before the Tropical Section of the Congress of the Royal Institute of Public Health held at Folkestone, July, 1904.

BY W. J. R. SIMPSON, M.D. ABERD.,
F.R.C.P. LOND.,

PROFESSOR OF HYGIENE, KING'S COLLEGE, LONDON; AND LECTURER ON TROPICAL HYGIENE AT THE LONDON SCHOOL OF TROPICAL MEDICINE.

GENTLEMEN,—My first duty is to convey to you my cordial thanks for the honour you have conferred on me in inviting me to be the President of the Tropical Section of this important Congress. Without further remark I shall proceed to the subject of my address—viz., Preventive Work in the Tropics.

HISTORICAL RÉSUMÉ OF ADVANCES IN TROPICAL HYGIENE.
